A NEW

THEORETICAL AND PRACTICAL TREATISE

ON

NAVIGATION:

IN WHICH THE

AUXILIARY BRANCHES OF MATHEMATICS AND ASTRONOMY,

COMPRISED OF

ALGEBRA, GEOMETRY, LOGARITHMS, PLANE AND SPHERICAL TRIGONOMETRY,
THE MOTIONS OF THE HEAVENLY BODIES, TIDES,
VARIATION OF THE COMPASS, ETC.,

ARE TREATED OF.

ALSO,

The Theory and most Simple Methods of Finding

TIME, LATITUDE AND LONGITUDE,

BY

CHRONOMETERS, LUNAR OBSERVATIONS, SINGLE AND
DOUBLE ALTITUDES, ARE TAUGHT.

BY M. F. MAURY,
LIEUT. U. S. NAVY.

PHILADELPHIA:
E. C. & J. BIDDLE, NO. 6 SOUTH FIFTH STREET.
1845.

DEDICATION.

TO

PROFESSOR BENJAMIN SILLIMAN.

SIR,

I BEG you will accept this little tribute of respect, as homage to your worth and talent by a stranger, and

Your obedient servant,

M. F. MAURY,
Passed Midshipman U. S. Navy.

Fredericksburg, Va., 30th April, 1835.

PREFACE TO THE FIRST EDITION.

The object of the present volume, is to place in the hands of students, and especially of the Midshipmen of the United States Navy, a Text Book, in which the theory as well as the practice of Navigation, is explained and taught.

It is not pretended that new theories are set forth, or that new principles are established in this work; but it is believed that those which have already been established, are here embodied in such a form, that the means of becoming a theoretical as well as a practical navigator, are placed within the reach of every student.

For this purpose the works of Bonnycastle, Colburn, Hutton, Legendre, Davies, Bowditch, Lardner, Hassler, Kelly, Keith, and La Place, have been consulted.

Care has been taken to introduce only those theorems upon which the problems in Navigation immediately depend, and which it is necessary to understand, in order satisfactorily to comprehend the principles of Mathematics and Astronomy, involved in the solution of these problems.

The fear of introducing more than is essentially requisite for this purpose, may have led to an error on the other extreme, by causing something to be omitted, which should have been inserted; but if such a fault be detected in the work, while it will be readily admitted on one hand to be a fault, it can scarcely be unjust on the other, to say that the error is on the safe side; especially when they who judge, are reminded, that there is not, throughout the whole work, a single principle laid down which does not serve at once as a rule, or as the basis of a rule, or as reference in some succeeding demonstration, position, or explanation, either to prove, establish, or elucidate; and moreover, that there are many, (perhaps the greater number,) of those for whose benefit the work is chiefly designed, who, during the whole period of their service at sea, never have the advantage of instruction from a teacher of Navigation; consequently they have to depend upon their own exertions, and the books before them, for their proficiency as Navigators. How necessary is it, then, that the work on Navigation for them, should be an elementary one, adapted to the capacity of all, and that it should not embrace the widest range; more particularly so, as there is not yet any regular system of education provided for the Navy.

The idea of such a work as the present, grew out of the author's own experience, and was suggested to him by his own wants while a student of Navigation; if it be not sufficient for the supply of similar wants on the part of others, it is hoped that it will, at least, serve to provoke some more capable pen to undertake and complete what is here attempted.

A more elementary work than any hitherto published on Navigation is much required as a school book in the United States. The attention of teachers of Navigation throughout the country is respectfully invited to it.

These pages were written chiefly on board of a man-of-war, in the midst of the various calls of duty, and the thousand interruptions incident to such a place; the author trusts that this circumstance will insure him on the part of his brother officers, and those into whose hands his work may fall, the indulgence usually claimed for inexperienced authors.

PREFACE

TO THE

THIRD EDITION.

THE present edition has been greatly enlarged and improved, and though much of it was written under a press of other business, the author hopes that it will be found not altogether unworthy the favour which has been extended to the first edition. The work is not all that the author would have it, or that the Navy requires it should be; yet it is believed to be better calculated than heretofore to meet the wants of the student of Navigation. Should there be errors in it, the author hopes that some allowance will be made for the peculiar circumstances, and the very great haste with which he has been compelled to prepare it.

Hydrographical Office, May 3d, 1845.

Digitized by Google

DECIMALS.

It is presumed that the student understands the first principles of common arithmetic. It is therefore taken for granted that he knows how to multiply and divide, add and subtract mixed quantities and vulgar fractions, as well as whole numbers. Wherefore we begin with DECIMALS.

1. Fractions are parts of a whole; and decimals are fractions of a whole that is divided into 10, or 100, or 1,000, or any other number of equal parts in the decimal scale of notation, as 10,000—10,000,000, etc.

2. The *denominator* of a decimal fraction, therefore, is seldom written, but is always understood to be unity (1.) with as many cyphers affixed as there are figures in the numerator: thus three-tenths is written .3 instead of $\frac{3}{10}$; three-hundredths, .03 instead of $\frac{3}{100}$; three-thousandths, .003 instead of $\frac{3}{1000}$; and so on:—the dot (.) (as .3) before the figure denoting it to be a *decimal* fraction, and not an *integer* or whole number.

This manner of expressing decimals is altogether conventional; but it has been generally adopted because it is convenient, and saves the trouble of writing the denominator, which, if written down, would make all logarithmic tables appear bungling, and, moreover, would render the process of log. calculations very tedious.

3. In whole numbers, the value of any quantity is increased by affixing cyphers: as 3, with cyphers affixed, becomes 30, 300, 3000, and so on, according to the number of cyphers; but the value is not altered by prefixing them: thus 3, 03, 003 or 0003, means but 3. The reverse is the case with decimals. Thus the decimal .3, with any number of cyphers affixed, remains of the same value, as .3, .30, .300, etc., all of which express the same part or portion of the whole. But the value of decimals is decreased by prefixing one or more cyphers: thus six-hundredths is written .06; six-thousandths, .006, and so on. And it is so expressed because of Rule 2, which requires the denominator to have as many *cyphers* in it as there are *figures* in the numerator. Thus to read the decimal .000004 we first count the figures in it, and then prefix unity (1) to as many cyphers as there are figures. In this decimal, there are six figures, therefore unity (1) prefixed to six cyphers, expresses the denominator of the above fraction, which is $\frac{4}{1.000.000}$ or four-millionths.

ADDITION AND SUBTRACTION.

4. When we add or subtract in whole numbers, we place units under units, tens under tens, and so on; or *beginning at the right hand we*

Digitized by Google

place the figures under those above in regular order. Thus, to add 1698 and 17, the figures are arranged:—

1698
17
1715

The reverse is the case with decimals; with them, we begin at the left, and arrange the left hand figures in regular order under those above. The reason is obvious—for as, by Rule 3, five-tenths, or .5 and .500000 are decimals of the same value, we consider and treat them as decimals having the same denominator, and consequently as consisting of the same number of figures in the numerator. If, therefore, in subtracting .05, which is equal to $\frac{1}{20}$, from .5, which is equal to $\frac{1}{2}$, we arrange the quantities as in whole numbers; thus, .5 / .05, we should be led into the error of making it appear that there is no remainder, or, in other words, that $\frac{1}{20}$ and $\frac{1}{2}$ are equal fractions. But if we arrange the left hand figures under each other; which is, in fact, calling the .5 tenths .50 hundredths, we shall then obtain the true difference, which is .45 hundredths; thus—

.5(0)
.0 5
.4 5

EXAMPLES.

Subtract .067 from .1

.1(00)
.0 6 7
Answer, .0 3 3

Subtract .79 from .8

.8(0)
.7 9
Ans. .0 1

Ex. From 1 2. 0 1
Subtract 3. 9(0)
Ans. 8 .1 1

from 6. 0 0 6
sub. 5. 0 1(0)
Ans. 0. 9 9 6

From 21.435
Sub. 18.546
Ans. 2.889

from 3 6. 4(00)
sub. 2 2. 0 06
Ans. 1 4 .3 94

from .2809
sub. .2761
Ans. .0048

Digitized by Google

ADDITION.

5. The same arrangement as to the left hand figures holds in addition.

EXAMPLES.

Ex.			
	To .2	to .09	to 60.9
	Add .0009	add .98	add 21.0004
	Ans. .2009	Ans. 1.07	Ans. 81.9004
	To 7.12	to 12.421	to 14.02
	Add 3.14	add 4.02	add 2.04
	Ans. 10.26	Ans. 16.441	Ans. 16.06

MULTIPLICATION.

6. Multiplication is performed as in whole numbers, only bearing in mind that the decimal part of the product must consist of as many places of figures as there are decimals in both the multiplier and the multiplicand together. The requisite number of figures for the product must be obtained, if necessary, by prefixing cyphers to the decimal part of it.

EXAMPLES.

Multiply	4.02	.6	.06	.06	.06	6.
By	.002	.4	.4	.04	.40	.4
Ans.	.00804	.24	.024	.0024	.0240	2.4
Multiply	4.12	6.05		5.02	5.00002	
By	.2	1.2		.003	.0004	
Ans.	.824	7.260		.01506	.002000008	
Multiply	45.4	16.12		8.5	1.01	
By	5.6	2.06		5.8	.001	
	2724	9672		680	.00101	
	2270	3224		425		
Ans.	254.24	33.2072		49.30		

DIVISION.

7. Division is also performed as in whole numbers. To fix the decimal point of the quotient, set off, for whole numbers, as many decimals from the dividend as there are decimals in the divisor, and divide. The quotient thus far is whole; for every additional figure in the divi-

Digitized by Google

dend, *including* those borrowed, set off a decimal in the quotient. Thus, to divide 2.4 by .2: set off .2 and .4 for whole numbers, and the problem is 24 ÷ 2 = 12. But 2.04 ÷ .2, when set off, is 20.4 ÷ 2 = 10.2. And .01 ÷ .4, when set off, is 0.1 ÷ 4 = 0.025.

EXAMPLES.

Ex. 1. Divide 15.841 by 5.24

```
5.24)15.84,1(3.023
     15.72
     ------
      1210
      1048
      ----
       1620
       1572
       ----
```

and so on, by borrowing cyphers, as long as there is a remainder.

Ex. 2. Divide 12.008 by .004

```
.004)12.008,(3002.0
```

Ex. 3. Divide .412 by .34

```
.34).41,2(1.2
    34
    --
    72
    68
    --
     4
     -
```

Ex 4. Divide .31 by 2.65. Here cyphers must be borrowed for the dividend (Rule 7) in order to carry on the division.

```
2.65).31,0000(.1169
     265
     ---
     450
     265
     ---
     1850
     1590
     ----
      2600
      2385
      ----
```

Ex. 5. Divide .27 by .54. Here again one or more cyphers must be borrowed for the dividend, in order to make division practicable.

```
.54).27,0(.5
    270
    ---
```

REDUCTION.

8. If we wish to convert a vulgar fraction, say $\frac{1}{4}$, into a decimal, it is plain that if we divide 100 into four equal parts, we shall have .25 as

Digitized by Google

the value of each of those parts. So if we wished to find the decimal to which $\frac{2}{5}$ is the equivalent: by taking the fifth of one hundred (=20) and multiplying it by 2, we should have the result = 40. Thus, 5)100(20×2 = 40. Therefore, if we divide 10,100, etc. by the denominator of a vulgar fraction, and multiply the quotient by the numerator, the product will be the decimal of the given fraction. But in the reduction of $\frac{2}{5}$: if instead of dividing 100 by 5, and multiplying the quotient by 2, we had affixed one or more cyphers to 2, and then divided by 5, we should have been led to the same result directly, and without the trouble of multiplication. Thus, 200 ÷ 5 = 40. Hence we obtain a more direct rule:

9. Affix one or more cyphers to the numerator, and divide by the denominator; the quotient is the decimal required.

EXAMPLES.

To reduce $\frac{1}{2}$ to a decimal, 1.0 ÷ 2 = .5

do. $\frac{4}{5}$ do. 4.0 ÷ 5 = .8

do. $\frac{7}{12}$ do. 7.000 ÷ 12 = .583

To reduce 2 hours to the decimal of a day, 24 hours make a day, therefore 2 hours make 2 of 24 parts, or $\frac{2}{24}$ of a day.

```
24)2.000(.083
   192
  ----
    80
    72
  ----
```

To reduce 8′ to the decimal of a degree, 60′ make 1°, wherefore 8′ = $\frac{8}{60}$ of a degree,

```
60)8.00(.13
   60
  ----
   200
   180
  ----
```

and so on of seconds to minutes, and of minutes to hours.

To reduce 5 days to the decimal of a year of 365 days: five days therefore is $\frac{5}{365}$ of a year.

```
365)5.0000(.01369
   365
  ----
  1350
  1095
  ----
  2550
  2190
  ----
  3600
  3285
  ----
```

Digitized by Google

To reduce 30 yds. to the decimal of a mile. A mile is 1760 yds.; therefore the fraction is $\frac{30}{1760}$ of a mile:

1760)30.000(.017
1760
12400
12320

To reduce 11 inches or $\frac{11}{12}$ of a foot to the decimal of a foot:

12)11.00(0.91

To reduce 3″ of longitude to the decimal of 1ˢ of time. One second of time (1ˢ) is equal to 15″ of longitude. The fraction therefore is $\frac{3}{15}$ of a second of time: 15)3.0(.2ˢ

10. The reverse of this operation is now readily understood, *i. e.*, of extracting from a decimal fraction the whole numbers which it contains, of the denomination next below; as the inches contained in .5 of a foot. Multiply the decimal by 12, because 12 inches make a foot, and we have 6 in. = 0.5 ft.

How many seconds of longitude (″) are in 0.4ˢ of time? Ans. 6″: 1ˢ = 15″; therefore 0. 4ˢ × 15″ = 6.″

ALGEBRA.

Digitized by Google

Digitized by Google

ALGEBRA.

DEFINITIONS.

§ I. ALGEBRA is a method of computation, in which magnitudes, or quantities, are represented by means of the letters of the alphabet. These letters have no positive or fixed value; they only stand for the quantities to be computed.

§ II. In algebra, known quantities are expressed either according to their numerical value, or by the first letters a, b, c, etc., of the alphabet.

§ III. And quantities of unknown value are usually represented by the last letters, x, y, z, etc.

§ IV. In algebraical computations, certain characters, called *signs*, have been introduced, and are used in the place of written words: thus,

$+$ (*plus*) is the sign of addition.

$-$ (*minus*) is the sign for subtraction.

$\times$ or . is the sign for multiplication.

$=$ is the sign of equality.

$\div$ is the sign for division.

$a + b - c \times d = x \div y$, or $\frac{x}{y}$, is read a plus b minus c multiplied by d equals x divided by y.

§ V. $a > b$ signifies that the former quantity (a) is greater than the latter (b).

$a < b$ signifies that the latter quantity (b) is greater than the former (a).

§ VI. (:) *is to* (: :) *as*, represents equality of ratio, and denotes proportion: thus $a : b :: c : d$, (read a is to b as c is to d), signifies that the ratio of a to b is equal to the ratio of c to d, and that these four quantities are proportional.

§ VII. $\backsim$ represents the difference between any two quantities between which it is placed: thus, $x \backsim y$ denotes the difference between x and y.

§ VIII. ∞ signifies that the quantity standing before it, thus, $x\infty$, is infinite in value.

§ IX. The numbers 2, 3, 4, etc., placed after a letter, thus, a^2, a^3, a^4, denote the 2d, 3d, 4th, etc., power of the quantity which that letter represents. The second power is the *square*, the third the *cube*, the 4th the *biquadrate:*

$$a \times a = a^2,$$
$$a^2 \times a = a^3,$$
$$a^3 \times a = a^4,$$

Digitized by Google

§ X. The numbers 2, 3, 4, etc., placed as above, are called the *indices* of the quantities to which they are affixed.

§ XI. The quantity which is a constant multiplier in the involution of a power, is called the root of that power: thus, (§ IX.,) a is the cube root of a^3, and the square root of a^2.

§ XII. $\surd$ is called the *radical* sign; and $\surd x$, or $\sqrt[2]{x}$, also $x^{\frac{1}{2}}$, denotes that the square root of x is the quantity alluded to; so $\sqrt[3]{y}$, or $y^{\frac{1}{3}}$, denotes the cube root of y: and so on with the other numbers, or with letters thus placed.

§ *a*. The number or letter placed over the radical sign, thus, $\sqrt[4]{}$, $\sqrt[n]{}$, or placed after any quantity, thus, $x^{\frac{1}{3}}$, 10^2, is called the exponent.

§ *b*. And a line drawn through any two quantities, denotes that those quantities cancel each other; thus, $a + b = 10 + b$, or $a \div b = 10 \div b$, denotes that b and b balance each other, and that $a = 10$.

§ XIII. A *surd* is a quantity to which the radical sign ($\surd$) is prefixed, and whose root cannot be expressed by numbers; thus, $\surd 3$, $\sqrt[3]{5}$, are surds.

§ XIV. A *term* is any quantity that is separated from another by a sign; thus, a, b and x, are terms in the compound quantity $a+b-x$.

§ XV. The number, (5,) or the letter, (c,) that is prefixed to any quantity, (5 a, or c a,) is called the *coefficient* of that quantity.

§ XVI. *Like quantities* consist of the same letters as $a\,b + 4\,a\,b - 2\,a\,b$.

§ XVII. *Unlike quantities* consist of different letters, as $x + 2\,y \times a + b$.

§ XVIII. When a quantity has no sign prefixed to it, +, (or *plus*,) is understood.

§ XIX. $\surd \overline{x^2 + y}$, or $(x^2 + y)^{\frac{1}{2}}$, denotes that these two quantities are as one, and that the square root of their *sum* is alluded to by the radical sign, or the exponent $\frac{1}{2}$. Thus, the square root of $64 + 36$, or $\surd\ 64 + 36$, is $8 + 36 = 42$, but the square root of $\overline{64 + 36}$, or $(64 + 36)^{\frac{1}{2}}$, under a *vinculum*, is 10, for $64 + 36 = 100$, and the square root of 100 is 10.

ADDITION.

§ XX. Addition is performed by collecting several quantities in a more simple form: $3\,a + 10\,a + a = 14\,a$, (read *fourteen times a*). 1 is understood to be the coefficient of every quantity that has no coefficient prefixed to it.

§ XXI. When the quantities to be cast up have unlike signs, the problem is solved, partly by addition and partly by subtraction. If the *negative* be greater than the *positive* quantities, the negative sign must be retained in the result. The sum of $6 - 10 + 9$, is 5; for 6 and 9 are here positive quantities, and make 15; and $15 - 10 = 5$: and the sum of $6 - 10 - 9$, is -13; for $-10 - 9 = -19$; and $-19 + 6$, or $6 - 19 = -13$. Every quantity, which has not a sign prefixed to it, is understood to be positive.

To add together, $4\,x - 9\,x + x + 3\,x - 5\,x$. Collecting all the

Digitized by Google

positive quantities into one sum, and all the negative quantities into another, then taking the less from the greater, the remainder, (prefixing the sign of the greater,) is the answer. Thus:

$$\begin{array}{r} 4x - 9x \\ x - 5x \\ 3x \\ \hline 8x - 14x = -6x \end{array}$$

$-6ay^2$	$10ba$	$-ac$
$4ay^2$	$2ba$	$7ac$
$9ay^2$	$-19ba$	$-9ac$
Ans. $7ay^2$	$-7ba$	$-3ac$

§ XXII. If all the terms be not *like* quantities, the positive and the negative of those that are like must each be added up separately; then these two sums must be subtracted, the one from the other, and the remainder thus obtained, connected by its proper sign to the *unlike* quantities, shows the answer. To add together:

$$\begin{array}{r} 4x + 6a - c^2 + 9y \\ -10x - 5a + c^2 - 5y \\ x - a + 4c^2 + 3y \\ 2x + 2a \\ \hline -3x + 2a + 4c^2 + 7y \end{array}$$

The positive x's are, $4x + x + 2x = 7x$; the negative are, $-10x$. The difference is, $(7x - 10x =)$, $-3x$. The positive a's are, $6a + 2a = 8a$; the negative are, $-5a - a = -6a$. The difference is, $(8a - 6a =)$, $2a$. The positive c^2's are, $c^2 + 4c^2 = 5c^2$; the negative is, $-c^2$. The difference is, $(5c^2 - c^2 =)$, $4c^2$. The positive y's are, $9y + 3y = 12y$; and the negative are, $-5y$. The difference is, $(12y - 5y =)$, $7y$.

To add together:

$$\begin{array}{r} \surd ab - a^2 + 2xy - 6x + 10a^2 - 9xy - a^2b + y - a \\ -\surd 6ab + 3a^2 + \surd 5ab - x + xy + a^2b - 4xy - 2x \\ a - c^2 + 4y - \surd 2ab - 2a^2 - 3xy + 4x + 14xy + a^2b \\ \surd ab - a^2 + 2xy + 6x - a^2b + a - c^2 + 4y \\ -\surd 6ab + 10a^2 - 9xy - x - 2a^2b + a + y \\ \surd 5ab + 3a^2 + xy - 2x + a^2b \\ -\surd 2ab - 2a^2 - 4xy + 4x \\ -3xy \\ 14xy \\ \hline -\surd 4ab + 20a^2 + 2xy + 2x - a^2b + 2a - 2c^2 + 10y \end{array}$$

Digitized by Google

To add together:

$$\begin{array}{l} y + a\,b + d\,x^3 - z^2\,a \\ y + c\,b + b\,x^3 - z^2\,x \\ \hline 2\,y + (a+c)\,b + (d+b)\,x^3 - z^2\,(a+x) \end{array}$$

To add together:

$$\begin{array}{r} a + b + c - x \\ 2\,a - b - 2\,c - 2\,x \\ -a + a\,b - c - 4\,x \\ \hline 2\,a + a\,b - 2\,c - 7\,x \end{array}$$

SUBTRACTION.

§ XXIII. Subtraction is the reverse of addition. The method of performing it consists in changing, or reversing, all the signs of the subtrahend, (i. e., making the positive negative, and the reverse,) and then proceeding as in addition; viz., by adding together like quantities that have like signs; and subtracting from each other like quantities that have unlike signs. The quantity or the quantities that result from this operation is the remainder.

To subtract $a - b$ from $a + b$

$$\begin{array}{rl} & a + b \\ \text{Changing the signs of the subtrahend} & a - b \\ \hline \text{The remainder} & = 2\,b \end{array}$$

This will be readily understood by ascribing a numerical value to a and b. Let $a = 6$ and $b = 4$; now subtract $6 - 4$ from $6 + 4$; $6 - 4 = 2$, and $6 + 4 = 10$, and $10 - 2 = 8$ (or twice $4 = 2\,b$.)

To subtract $a + b$ from $a - b$.

$$\begin{array}{r} a - b \\ a + b \\ \hline -2\,b \end{array}$$

To subtract:

$$\begin{array}{r} 2\,x\,y + b^2\,c - 3\,a \\ x\,y - b^2\,c + a \\ \hline x\,y + 2\,b^2\,c - 4\,a \end{array}$$

To subtract:

$$\begin{array}{r} 10\,x - y - a\,c \\ -3\,x - 2\,y - 4\,a\,c \\ \hline 13\,x + y + 3\,a\,c \end{array}$$

MULTIPLICATION.

§ XXIV. In the multiplication of letters, the product of any two factors is obtained and expressed by prefixing, as coefficients, the several letters contained in the multiplier, to those of the multiplicand. Thus:

$$\begin{array}{r} x + y \\ \text{by } a + b \\ \hline a\,x + a\,y + b\,x + b\,y. \end{array}$$

Digitized by Google

§ XXV. Multiplication is denoted thus, $a \times b$; or thus, $a \,.\, b$; or thus, $a\,b$.

† 1. By recollecting that a times b, and b times a, are expressions for the same product, just as 4 times 9, and 9 times 4, express the same number, it will at once be understood how there is no difference in the value of the quantity, whether it be expressed $a\,b$, or $b\,a$. But when several letters are contained in the same term, as $a \times c \times b$, it is generally expressed by the letters arranged in alphabetical order; thus, $a\,b\,c$.

§ XXVI. To multiply $x + y$ by $a - b$. Ans. $a\,x + a\,y - b\,x - b\,y$.

When terms of *unlike* signs are multiplied together, their product is negative, and (—) must be prefixed to it.

§ XXVII. The product of $x + y$ by $x + y$ is $x^2 + 2\,x\,y + y^2$, or $x\,x + x\,y + x\,y + y\,y$. The former, being the shorter method of writing it, is the better. The small figures that are affixed show how many times the letter with which they are connected enters as a factor in the term.

§ XXVIII. The product of $x + y$ by $-x - y$, is $-x^2 - 2\,x\,y - y^2$.

§ XXIX. The product of $x + y$ by $x - y$, is $x^2 - y^2$; for x, y occurring twice in the product, and with unlike signs, (+ and —), (§ XII. § *b*.) cancels itself.

To multiply $x^2 - y^2 + 3\,x\,y$
by $x + y$

$$x^3 - x\,y^2 + 3\,x^2\,y$$
$$x^2\,y - y^3 + 3\,x\,y^2$$
$$x^3 + 2\,x\,y^2 + 4\,x^2\,y - y^3$$

§ XXX. Unless the quantity be under a vinculum, (§ XIX.,) the index applies only to that letter with which it is in juxta-position. The term $x\,y^2$ denotes the product of x and y^2; and $x^2\,y$ denotes the product of the two factors x^2 and y. The term $(x\,y)^2$, or $\overline{x\,y}^2$, denotes the square of the product of the two factors x and y. Let $x = 4$ and $y = 3$: $x^2 = 16$ and $y^2 = 9$. The value then of the first term $(x\,y^2)$ is 4×9 $(= 36;)$ of the second, $(x^2\,y)$, is 16×3 $(= 48;)$ and of the third, $(\overline{x\,y}^2,)$ is the square of the product, (12,) and of 3 and 4, $(= 144.)$

To multiply $a\,x + a\,b - a^2$
by $a + x + b$

$$a^2\,x + a^2\,b - a^3$$
$$a\,x^2 + a\,b\,x - a^2\,x$$
$$a\,b\,x + a\,b^2 - a^2\,b$$
$$a\,x^2 - a^3 + 2\,a\,b\,x + a\,b^2$$

Digitized by Google

To multiply $-5a-4x$
by $2-a-x$

$$-10a-8x$$
$$5a^2+4ax$$
$$5ax+4x^2$$

$$-10a+5a^2-8x+9ax+4x^2$$

§ XXXI. When the same letter enters into both factors, the product is obtained by adding the indices or exponents of the letter, as $a^3 \times a^2 = a^5$; for $3+2$ is 5. And $x \times x$ is x^2; 1 (§ XX.) is the index and coefficient of every letter which has no other index or coefficient expressed.

DIVISION.

§ XXXII. Division is the converse of multiplication.

4 times b divided by 4 gives b. So a times b divided by a gives b.

$$4ax \div 2x = 2a$$
$$4ax \div 2a = 2x$$

§ XXXIII. Division being the converse of multiplication, the product of the divisor by the quotient gives the dividend. Thus, $2x \times 2a = 4ax$.

§ XXXIV. When the divisor and dividend are powers, or are roots, of the same quantity, the index or exponent, of the dividend, minus that of the divisor, is the quotient. Thus, $x^3 + x^5 \div x^2 = x + x^3$.

§ XXXV. When all the terms of the dividend have letters that are common to the divisor, the operation of dividing is performed by striking out from the dividend the letters of the divisor, and dividing the coefficients. Thus,

$$8xy \div 2y = 4x$$
$$12axz \div 3ax = 4z$$
$$6xy^2z \div 2xy = 3yz.$$

§ XXXVI. Division is sometimes expressed without being performed, as $x+y \div a$, or $\frac{x+y.}{a}$

§ XXXVII. This last quantity is a fraction. Fractions in algebra are multiplied, divided, etc., after the same manner by which such operations are performed in common arithmetic.

EQUATIONS.

§ XXXVIII. Two or more quantities, with the sign (=) of equality between them, constitute an equation; as $x + 10 = 14 + 6$.

Digitized by Google

§ *a*. And if any two of those quantities, which constitute an equation, be known, the other is also known. Thus, if $a \times b = x$, the value of x is necessarily known. If in this equation, b be the unknown quantity, a and x the known ones, the expression $\frac{x}{a} = b$, gives it to us. So of a.

§ XXXIX. All the quantities or terms that are on either side of the sign (=) constitute a *member* of the equation; $x + 10$ is the *first*, and $14 + 6$ is the *second* member of the equation $x + 10 = 14 + 6$. The two members, necessarily, are always equal to each other.

§ XL. In the process of solving or reducing an equation, the known quantities, or terms of the equation are all collected and arranged with their proper signs, in one member of the equation, and the unknown quantities in the other member, as $x = 14 + 6 - 10$. The value of x in this equation is therefore equal to 10.

§ XLI. In transposing a term from one member to another, the equality of the two members of the equation is preserved, by *changing* the *sign* of the term transposed. By transposition, *positive* terms become *negative*, and the reverse; also the sign ($\times$) of multiplication becomes ($\div$) the sign of division, and vice versâ. Thus, in the equation above $x + 10 = 20$, (or $6 + 14$:) by transposition $x = 20 - 10$. Also, in the equation $12 \times 4 = 8 \times 6$, by transposing we have $\frac{12}{6} = \frac{8}{4}$; and the equation $a \div b = x \div y$, by transposition, becomes $a \times y = x \times b$.

§ *a*. So also $\frac{10}{5} = 2$, by transposition becomes either $\frac{10}{2} = 5$, or $10 = 5 \times 2$.

To find the value of x in the equation $a + x - c = b + 14$; by transposing a and $-c$, and changing their signs, the value of x is obtained: it stands thus, $x = b + 14 - a + c$.

EXAMPLES.

Ex. $a - x^2 + y = 90 + a - 40$. To find y; a being in each member, and having the same sign, cancels itself, and may therefore be stricken from the equation; for if transposed, the expression would be $a - a$, which two balance each other. The value of y is obtained then, by transposing $-x^2$, when the equation stands thus, $y = 90 - 40 + x^2$; in its most simple form, thus, $y = 50 + x^2$.

Ex. $8x - 10 = 80 + 2x$. To find x; transposing and placing the known and unknown quantities on opposite sides, the equation stands, $8x - 2x = 80 + 10$. Subtracting and adding, it becomes $6x = 90$; and $x = 15$, (by division).

Ex. $x \div 2 + 10 = 14 + 8$. To find x; $\frac{1}{2}x$ or $\frac{x}{2} = 14 + 8 - 10$. The value of the second member of the equation is 12; therefore $\frac{x}{2} = 12$; and by multiplication, $x = 24$.

From the last two examples, this general conclusion may be drawn, viz:

Digitized by Google

§ XLII. When a multiplier of either member is transposed, it becomes divisor to the other member; and vice versâ.

Ex. $8x^2 + ax - 10x = 14x + 4x^2 + 16x$. To find x. x is common in every term of each member of the equation. Then, dividing by x, the equation becomes $8x + a - 10 = 14 + 4x + 16$; transposing and placing all the x terms alone in one member, $8x - 4x = 14 + 16 + 10 - a$; subtracting and adding, $4x = 40 - a$; dividing, $x = 10 - \frac{a}{4}$.

Ex. $3bx - 9ab = 3y$. To find x. Transposing, $3bx = 3y + 9ab$; dividing, $x = \frac{3y + 9ab}{3b} = \frac{y}{b} + 3a$. Therefore, $x = \frac{y}{b} + 3a$.

Ex. $\frac{x}{3} + \frac{x}{2} = 10$. To find x. Clearing the equation of fractions; 1st, $x + \frac{3x}{2} = 30$; 2d, $2x + 3x = 60$; adding, $5x = 60$; dividing, $x = 12$.

§ XLIII. Thus an equation is cleared of fractions *by multiplying every term* (except the fraction itself) *by the denominator.*

Ex. 1. The commander of a man-of-war is desirous of having his ship calked, that he may proceed on his voyage. His own calkers can finish the job of calking in 10 days. But he employs a gang from the shore, that could finish the whole work in 6 days, to assist his. How many days' job are there for both gangs together?

Let x denote the job of work. Then $\frac{x}{10}$ is one day's work for the ship's calkers; $\frac{x}{6}$ is one day's work for the shore gang; and $\frac{x}{10} + \frac{x}{6}$ = 1 day's work for both gangs together. Clearing this equation of fractions, $6x + 10x = 60$; and $16x = 60$, or $x = 3\frac{12}{16}$, the number of days.

Ex. 2. A vessel, after an engagement, could muster only 238 able-bodied men; on examining her list of sick and wounded, she found her loss in killed to be $\frac{1}{5}$ of her whole crew, and in wounded $\frac{1}{3}$ of the whole crew. What crew had she when she went into action?

Let x denote her crew when the action commenced. Thus, $\frac{x}{5} + \frac{x}{3} + 238 = x$. Clearing the equation of fractions, $3x + 5x + 3570 = 15x$; transposing, $3570 = 7x$, or $510 = x$, the whole crew when the action commenced.

§ XLIV. When the value of more than one unknown quantity is required, the problem, if definite, comprises conditions for as many equations as there are quantities required. In such cases the unknown quantities (x, y, z, etc.) have the same value in all the equations; i. e., x in one equation is equal to x in another of the same set. When the value of x, y, or z, is found, its value is substituted in its stead.

Digitized by Google

Ex. $\left.\begin{array}{l} x + y = 44 \\ x - 3y = 36 \end{array}\right\}$ To find x and y; $x = 44 - y$ and $x = 36 + 3y$; thus $44 - y = 36 + 3y$; transposing, $4y = 8$, or $y = 2$; and substituting, $x = 44 - y$, or $x = 42$.

Ex. $\left.\begin{array}{l} x + y + z = 60 \\ x + 4y + 3z = 144 \\ 2x + y + 8z = 132 \end{array}\right\}$ To find x, y, and z; $x = 60 - y - z$; $x = 144 - 4y - 3z$; and $x = 66 - \frac{y}{2} - 4z$. Eliminating x; $60 - y - z = 144 - 4y - 3z$; and $144 - 4y - 3z = 66 - \frac{y}{2} - 4z$. Transposing, to find the value of y; $3y = 144 - 60 - 2z$, or $y = 28 - \frac{2z}{3}$; again, $7y = 288 - 132 - 8z + 6z$, or $y = \frac{156 - 2z}{7}$; eliminating y, $28 - \frac{2z}{3} = \frac{156 - 2z}{7}$; clearing the equation, $14z - 588 = 468 - 6z$; transposing, $20z = 120$ or $z = 6$.

For z, in the equation $y = 28 - \frac{2z}{3}$, substituting its value (6), $y = 28 - 4$, or $y = 24$. And for z and y, in the equation $x = 60 - y - z$, substituting their values (24 and 6), $x = 60 - 24 - 6$, or $x = 30$.

PROPORTIONS.

§ XLV. There is another manner of expressing certain equations which do not involve more than 4 terms, and when thus expressed, the terms are said to be *proportional.* Thus the proportion $3 : 4 :: 6 : 8$, is but another method of expressing the equation $3 \div 4 = 6 \div 8$, or $\frac{3}{4} = \frac{6}{8}$. The dots (:) being an abbreviation of the sign ($\div$) of division; and the dots (: :) being another form for expressing the sign (=) of equality, to show that the *ratio* between the quantities on each side of it is the same.

§ XLVI. Whence it may be inferred, as a general rule, that *if the quotient of two quantities be equal to the quotient of two others,* these four quantities are proportional. And,

† 1. That the ratio between either divisor and its dividend is equal to the ratio between the other divisor and its dividend.

§ XLVII. By this rule we have $4 : 3 :: 8 : 6$, for $\frac{4}{3} = \frac{8}{6}$. This form of expression for the proportion $(3 : 4 :: 6 : 8)$ first quoted, is called "*invertendo,*" (from inverting the divisor and dividends,) thus $3 \div 4 = 6 \div 8$, and *inversely* $4 \div 3 = 8 \div 6$.

§ XLVIII. By the same rule we also have $3 : 6 :: 4 : 8$. This form of expression for the proportion $(3 : 4 :: 6 : 8)$ is called "*alternando,*" for by taking the terms *alternately* we have $3 \div 6 = 4 \div 8$.

§ XLIX. Whence also another general rule in proportions: that, if four quantities be proportional, they are also proportional when taken *inversely,* or when taken *alternately.*

§ L. $3 \div 4 = 6 \div 8$, by transposition $3 \times 8 = 6 \times 4$; wherefore, also, if the product of two factors be equal to the product of two other factors, those four factors are proportional, as $3 : 6 :: 4 : 8$.

GEOMETRY.

PART I.

Digitized by Google

Digitized by Google

GEOMETRY.

DEFINITIONS.

§ 1. *A point* is an atom of space.*

§ 2. *A line* (———) is length without breadth.

§ *a.* The track of a moving point would be a line.

§ *b.* The extremities of every line are points.

§ *c.* A line may be of any length.

§ *d.* Lines are either straight or curved.

§ 3. *A straight* or *right line* (———) is the shortest line that can be drawn from one point to another.

§ *a.* If two lines meet each other they form an angle. 
§ 4. *A plane* is an extent, (as the surface of this page), on which the straight line will lie that joins any two points which are in that extent.

§ *a.* A plane is without thickness, and it may be of any length and breadth.

§ *b.* The limits of every plane are lines.

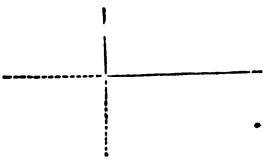
§ *c.* If two planes cross each other, the line of their intersection is a straight line.

§ 5. Two lines diverging from, or meeting in, the same point, form an *angle.* 
§ *a.* The point in which the lines join or cross each other, is called the *angular point.*

§ *b.* Angles are either right, acute, or obtuse.

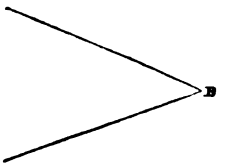
* I have preferred this definition because of its analogy. If we suppose an *atom of space* to be to space what an atom of matter is to matter, i. e., the ultimate particle, and incapable of division—and if we suppose such ultimate particle of matter to be put in motion, its path would be represented by a line; if we suppose this line to move sidewise, its path would be represented by a plane or a superficies; and if again we suppose this superficies to move in a direction perpendicular to its own plane, we should thus have a solid, or the dimensions of length, breadth and thickness generated from a particle of matter *without magnitude*, were it possible to conceive of such. So from a point, as the ultimate atom of space, we may conceive all the elements of extension to be derived; thus a point (§ 2, § *a.*) put in motion would describe a line, and this line, moving sidewise, would describe a plane, and this plane, moving in a direction perpendicular to its last motion, would describe all the dimensions of space.

Digitized by Google



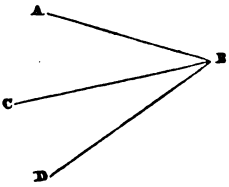
§ 6. When one straight line stands upon another, without inclining to either side, the angle, or angles, which these two lines form, are called *right* angles.

§ *a*. All right angles are equal, and every one contains 90° (*degrees*). (Vide § 49, § *d*.)



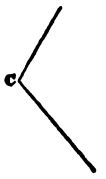
§ *b*. Straight lines that form right angles with each other, are said to be *perpendicular* the one to the other; and those that are perpendicular are at right angles with each other.

§ 7. Every angle which is *less* than a right angle, is an *acute* angle.



§ *a*. Angles are generally particularized by means of letters; as the angle B. But when there are more angles than one at the same angular point, the angle to be particularized is made known by placing the letter at the angular point *between* the letters which stand for the lines that form the angle. As the angle A B C, or C B D.

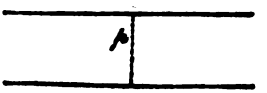
§ 8. Every angle which is *greater* than a right angle is an *obtuse angle;* as the angle C.



§ *a*. An *oblique angle* may be either acute or obtuse.

§ *b*. Two angles are equal, when they contain the same number of degrees (°), minutes (′), and seconds (″), or when the lines which form an angle have the same divergence from each other, which the lines have that form the other angle.

§ *c*. The difference between an oblique angle and a right angle is the *complement* of the oblique angle.



§ 9. *Parallel lines* are lines that have always the same distance between them. They lie in the same direction, and if lengthened, *ad infinitum*, would neither approach, nor recede from, each other.

§ *a*. The distance of two parallel lines from each other is measured by any straight line (*p*) that may be drawn between them, perpendicularly from one to the other.

§ 10. *A figure* is any extent bounded by one or more lines, or surfaces.

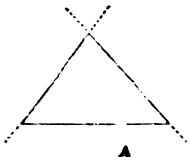
§ *a*. The space included by a figure is called its *area*.

§ 11. *A superficies* is the surface of a figure.

§ *a*. A superficies and a plane coincide, when a straight line, that joins any two points in the superficies, lies on that surface. The superficies of a figure is limited to the extent of the surface of that figure; but its plane is infinite.

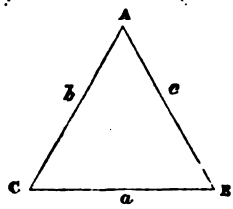
§ *b*. When the superficies and the plane of a figure coincide, the former is called a *plane* superficies.

Digitized by Google



§ 12. *A plane triangle* is a figure that is formed by the intersection of three straight lines, any two of which intersect the other in different points.

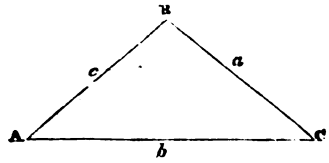
§ *a*. The intercepted parts of these lines are called the sides of the triangle.



§ *b*. Every triangle has six parts; viz., three sides, and three angles.

§ *c*. Triangles, with regard to their sides, are either equilateral, isosceles, or scaline; with regard to their angles, they are either acute, right, or obtuse angled.

§ 13. *An equilateral triangle* has its sides all equal to each other; viz., *b* equal to *a* or *c*.



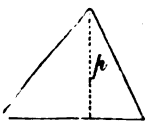
§ 14. An *isosceles triangle* has two equal sides, as *c* and *a*.

§ *a*. An isosceles triangle may be either acute, right, or obtuse angled. Its third side (*b*) is its base.

§ 15. A scaline triangle has none of its sides equal.

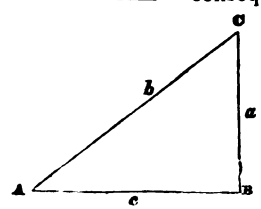
§ *a*. A scaline triangle may also be right or oblique angled.

§ 16. An *acute* angled triangle has each of its angles less than a right angle.



§ *a*. The *vertex* of a triangle is the angle that is opposite to the base of the triangle.

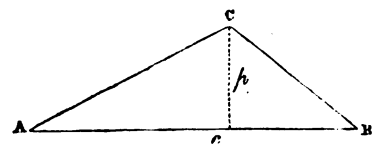
§ *b*. Any angle may be called the vertical angle, and consequently any side may be made the base.



§ 17. A *right angled triangle* has an angle (B), that is a right angle.

§ *a*. The side (*b*) which subtends the right angle, is called the *hypothenuse;* the two other sides (*c* and *a*) are called *legs*.

§ 18. An *obtuse angled triangle* has an angle (C) that is obtuse.

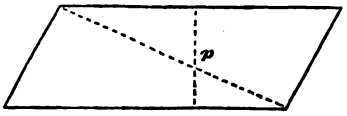


§ *a*. The *altitude* of a triangle is the perpendicular distance (*p*) of the vertical angle (C) (§ 16, § *b*.) from the base (*c*.) The base must be produced to meet the perpendicular, if the perpendicular fall without the triangle.

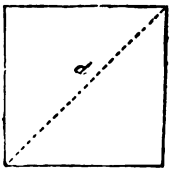
§ *b*. As any side (§ 16, § *b*.) may be made the base of a triangle, the perpendicular distance of any angle from its opposite side may be called the altitude, or height of the triangle.

§ 19. A *parallelogram* is a right lined (§ 3.) quadrilateral figure, the opposite sides of which are equal and parallel.

Digitized by Google



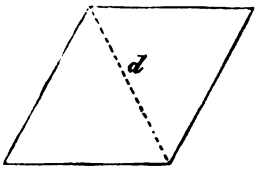
§ *a*. The *altitude* of a parallelogram is the distance (*p*) (§ 9. § *a*.) between either pair of its opposite sides. To show the altitude of a parallelogram, either of two opposite sides may be produced until it meets, at right angles, a perpendicular from the other side.



§ *b*. The measure or *area* of a parallelogram, is the product of its length and breadth, or of its base and altitude.

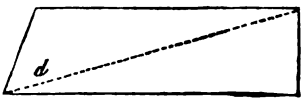
§ *c*. Any side of a parallelogram may be made its base.

§ 20. A *square* is a parallelogram, of which all the sides are equal and all the angles right angles.



§ *a*. Every angle of a square is, therefore, a right angle.

§ 21. A *rhombus* is a parallelogram that has all of its sides equal to each other; but its angles are not right angles.



§ 22. A *trapezoid* is also a four-sided figure, but only two sides of it are parallel, though they are not equal.

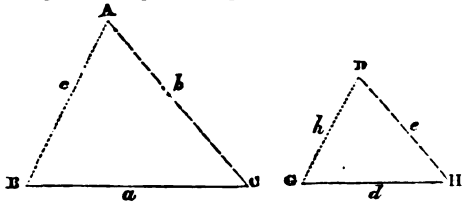
§ *a*. A diagonal is a straight line (*d*) that joins two opposite angles in a four-sided figure.

§ *b*. The space included by a parallelogram is called (§ 10. § *a*.) its area or measure, and is expressed (§ 19. § *b*.) by the product of its base and altitude.

§ 23. Two figures are *equal* when every *part* in one is equal to the part in the other, which corresponds to it; and two equal figures are always of the same magnitude.

§ *a*. And two figures are of the same *magnitude* when their areas are equal: a triangle and a parallelogram may be of the same magnitude, but they cannot be equal. A triangle only can be equal to a triangle; a parallelogram to a parallelogram, etc.

§ *b*. Two figures are *similar* when every *angle* in one is equal to the angle which corresponds to it in another figure. Figures only of the same class are similar, viz.: triangles are similar to triangles, parallelograms to parallelograms, etc.



§ *c*. *Homologous* sides, or angles, are the sides, or angles, which in two equal or similar triangles, correspond by their relative positions to each other; thus *c* and *h* are homologous sides, also *b* and *e*, and *a* and *d*.

Digitized by Google

§ *d.* Homologous angles are equal to each other. B and G are homologous angles; so also are A and D, and C and H.

AXIOMS.

§ 24. *Axioms* are self-evident truths, such as:

§ *a.* Things that are equal to the same, or to equal things, are themselves equal.

§ *b.* If equals be added to, or subtracted from, or substituted for, multiplied or divided by, the same or equal quantities, the sums or remainders, quotients or products, will be equal.

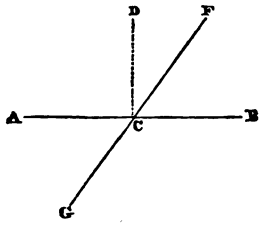
§ *c.* A part is less than the whole.

§ *d.* All of the parts are equal to the whole, and the whole to all of its parts.

PROPOSITIONS.

PROPOSITION I.

§ 25. Two straight lines which cross each other, make the two angles that are on the same side of either line, either two right angles, or equal to two right angles.



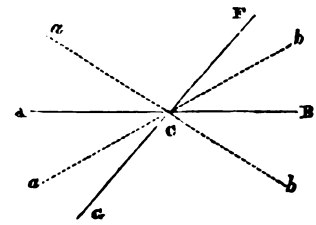
§ *a.* Let A B and F G be two straight lines that cross each other in C; the two angles (F C A, F C B) on the same side of either line (A B) are either two right angles, or are equal to two right angles.

§ *b.* If A B and F G be perpendicular to each other, they cut each other at right angles (§ 6. § *b.*); and consequently each of the angles F C A and F C B is a right angle. But if A B and F G be not perpendicular to each other: from C, the point of their intersection, draw C D, which shall be perpendicular to (A B) one of them, then will D C A and D C B, the whole angular space from C, on one side of A B, be two right angles (§ 6. § *b.*); F C A and F C B, together, also comprehend the same angular space; therefore they are equal to D C A + D C B (§ 24. § *c.*) which are two right angles. In a similar manner, it may be proven, that B C F + B C G, or G C B + G C A, or A C G + A C F, are equal to two right angles.

PROPOSITION II.

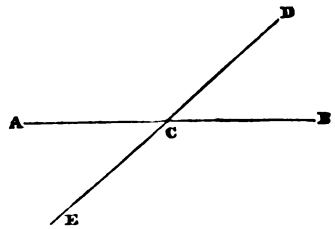
§ 26. All the angles, that any number of straight lines, which cross each other in the same point, make with each other, are together equal to four right angles.

Digitized by Google



§ *a*. Since the two angles (§ 25.) F C A, F C B, are equal to two right angles; and also G C B, G C A, are equal to two right angles; the four angles F C A, F C B, G C A, G C B, which two straight lines make by crossing each other, are equal to four right angles. If these four angles be divided into any number of other angles, by straight lines *a b*, *a b*, crossing in the point C, the sum of the divisions thus made will be equal (§ 24. § *d*.) to four right angles.

PROPOSITION III.

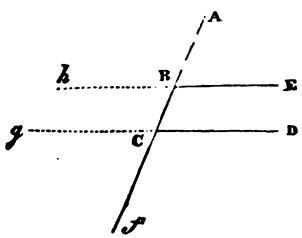


§ 27. When two straight lines A B, D E, cross each other, they make the angles D C B and A C E, or A C D and B C E, that are vertically opposite, equal to each other.

§ *a*. The angles A C D and D C B, (§ 25.) are together equal to two right angles; by the same proposition A C D + A C E, are also equal to two right angles; wherefore (§ 24. § *c*.) A C D + D C B = A C D + A C E; and A C D is a term in each member of the equation, and being taken away or cancelled, we have (§ 24. § *b*.) D C B = A C E.

§ *b*. It may be demonstrated in a similar manner, that the vertical and opposite angles A C D and B C E, are equal to each other.

PROPOSITION IV.



§ 28. When a straight line (A C) crosses two others (B E and C D) that are parallel, it makes the angles (A B E and A C D), which are on the same side of the two lines, equal to each other.

§ *a*. If the straight line A C cross the two others perpendicularly, the proposition becomes evident, for the angles formed would be (§ 6. § *b*.) right angles, and consequently equal.

§ *b*. But if they cross obliquely, it is obvious that if two lines be parallel to each other, they must have the same divergence from any straight line which crosses them; wherefore (§ 8. § *b*.) A B E = A C D; for B E and C D have the same divergence from A C.

§ *c*. In the same manner it may be shown that E B *f* is equal to D C *f*.

§ *d*. The angles (A B E, *h* B *f*, A C D, *g* C *f*, etc.) taken alternately on each side of A *f*, are called *alternate* angles.

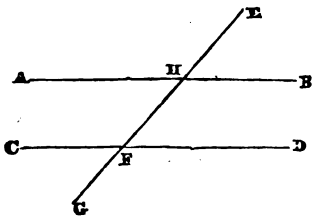
Digitized by Google

§ *e*. The angles (A B *h*, A B E, *f* C *g*, and *f* C D,) on the outside of the two parallel lines are called the *external* or *exterior* angles.

§ *f*. And the others are called *internal* or *interior* angles.

PROPOSITION V.

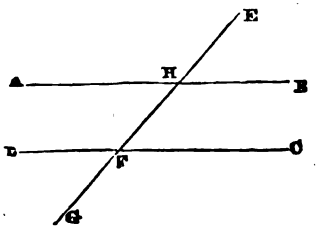
§ 29. A right line that crosses two others which are parallel, makes the interior angles (§ 28. § *f*.) (A H G and D F E) that are alternate (§ 28. § *d*.) equal to each other.



§ *a*. A H G and E H B are opposite and vertical angles, wherefore (§ 27.) they are equal to each other, and E H B (§ 28.) is equal to D F E; therefore (§ 24. § *a*.) A H G is equal to D F E.

§ *b*. In the same manner it may be proven that the alternate and interior angles B H F and C F H are equal to each other.

PROPOSITION VI.



§ 30. If a straight line cross two others that are parallel, it makes the sum of the two internal angles (B H F and H F C) that are on the same side of it, equal to two right angles; and the alternate (§ 28. § *d*.) angles (E H B, A H F, H F C, and D F G) equal to each other.

§ *a*. The angles B H E and B H F (§ 25.) are together equal to two right angles, and (§ 28.) B H E is equal to H F C, therefore (§ 24. § *b*.) the internal angles (B H F and H F C) that are on the same side of E G, are together equal to two right angles.

§ *b*. The alternate angle E H B = A H F, and H F C = D F G, because (§ 27.) they are vertically opposite; and (§ 29.) A H F = H F C; wherefore (§ 24. § *a*.) the alternate angles E H B, A H F, H F C, and D F G, are equal to each other.

§ *c*. After the same manner of demonstration, it may be proven that the alternate angles, A H E, B H F, H F D, and C F G, are equal to each other.

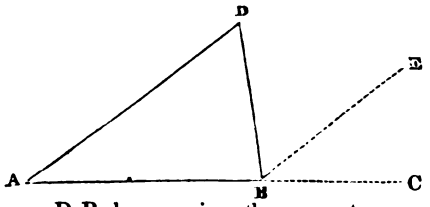
§ *d*. *Cor*. If a straight line (E G) cross two others (A B and D C) so as to make the sum of the internal angles (§ *a*.) (B H F and H F C) on the same side of it, equal to two right angles; or the alternate angles (§ *b*.) (E H B, A H F, H F C, and D F G,) equal to each other; or an exterior angle (§ 28.) (E H B) equal to its alternate and internal angle (H F C), these two straight lines are parallel.

PROPOSITION VII.

§ 31. The exterior angle (D B C) which is formed by producing any

Digitized by Google

side (A B) of a triangle, is equal to the two interior and remote angles (A and D) of the triangle.



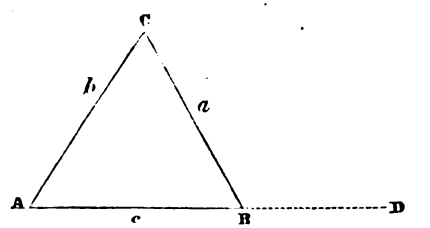
§ *a*. From B let B E be drawn parallel to A D; also let A B be produced to C.

§ *b*. Because A D and B E are parallel (§ *a*.) and A C crosses them, the angles A and E B C (§ 28.) are equal to each other; moreover D B, by crossing the same two parallels (D A and B E), makes (§ 29.) the alternate and interior angles (D and D B E) equal to each other; the exterior angle D B C is made up of D B E and E B C, then substituting the whole for its parts (§ 24. § *d*.) we have (§ 24. § *b*.) the exterior angle D B C = A + D, the two interior and remote angles in the triangle A D B.

§ *c*. If either of the two other sides be produced, the proposition is proven in the same way.

PROPOSITION VIII.

§ 32. The sum of the angles of a triangle is 180°, or two right angles.



§ *a*. Produce a side (*c*) of any triangle to D. Then C B A and the exterior angle C B D (§ 25.) are equal to two right angles: and the exterior angle C B D, (§ 31.) is equal to the two remote angles C and A: therefore (§ 24. § *b*.) C, A, and C B A are equal to two right angles: and C, A, and C B A are the three angles of the triangle (A C B) proposed.

§ *b*. *Cor*. If two angles of one triangle be known, the third is also known. It is found by subtracting the sum of the two known angles from 180°.

§ *c*. *Cor*. And the two acute angles of a right angled triangle (§ 17.) are together equal to one right angle.

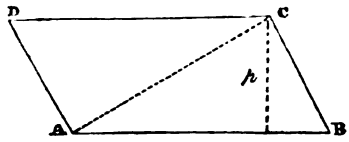
§ *d*. Wherefore the acute angles of any right angled triangle are the complements (§ 8. § *c*.) of each other.

§ *e*. It is also evident from the above, that if two angles in one triangle be equal to two angles of another, the remaining angles are also equal to each other.

PROPOSITION IX.

§ 33. A diagonal (A C) of a parallelogram, divides the parallelogram into two equal (§ 23.) triangles (A C D and A C B).

Digitized by Google



§ *a.* The opposite sides of a parallelogram (§ 19.) are parallel and equal to each other; wherefore D C = A B, A D = C B, and A C is common to the two triangles (A C D and A C B); therefore their sides are equal, those of the one to those of the other. The angles D C A and C A B are equal to each other (§ 30.), for they are alternate angles (§ 28. § *d.*) made by A C crossing the two parallels D C and A B. For the same reason the alternate angles D A C and A C B made by A C with the parallels A D and C B, are equal to each other. Wherefore, the two angles (D C A and D A C) in one triangle being equal to two angles (A C B and C A B) in another, the remaining angles (D and B) (§ 32. § *e.*) are also equal to each other. Therefore, the triangle A C D having its sides and angles respectively equal to the sides and angles of the triangle A C B, is equal (§ 23.) to the latter, and the diagonal (A C) divides the parallelogram D A B C into these two equal triangles.

§ *b.* Scholium. The area (§ 10. § *a.*) of a parallelogram (§ 19. § *b.*) is the product of its base and altitude. The triangle A B C and the parallelogram D A B C have the same base (A B) and altitude (*p*) and the triangle is proven to be *half* of the parallelogram; therefore,

§ *c. Cor.* The area or magnitude of a triangle is the product of its base by *half* its altitude.

§ *d. Cor.* The triangles into which a diagonal divides a parallelogram are both equal and (§ 23.) of the same magnitude.

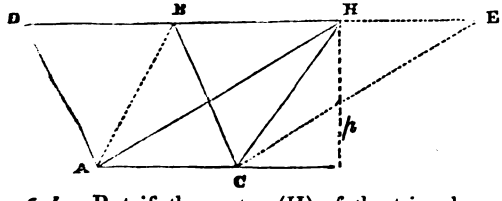
§ *e.* Scholium. D A C + B A C (§ *a.*) = D C A + B C A, and D = B. Therefore,

§ *f. Cor.* The opposite angles of a parallelogram are equal.

§ *g. Cor.* If the opposite angles of a quadrilateral figure be equal, the figure is a parallelogram.

PROPOSITION X.

§ 34. If a parallelogram (D A C B) and a triangle (A B C) stand upon the same base (A C), and between the same parallels (D B and A C), they have the same altitude (*p*) and the triangle is equal to *half* the parallelogram.



§ *a.* If one side (A B) of the triangle be diagonal to the parallelogram, the triangle falls within the parallelogram, and (§ 33.) the proposition is proven.

§ *b.* But if the vertex (H) of the triangle proposed, fall without the parallelogram, as A H C, continue one of the parallels (D B) on, through the vertex H, to E; and upon the base A C construct the parallelogram A H E C, to which the side H C of this triangle is

Digitized by Google

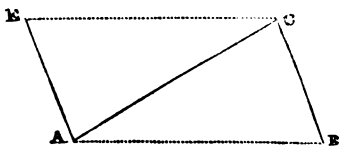
diagonal (§ 22. § *a.*), therefore A H C (§ 33.) is half of the parallelogram A H E C. The parallelograms A H E C and D A C B (§ 19. § *a.*) have the same base (A C) and altitude (*p*), and the area of each (§ 19. § *b.*) is the product of A C by *p*; wherefore (§ 24. § *b.*) these two parallelograms are of the same magnitude; therefore (§ 24. § *a.*) the triangle A H C is also equal in *magnitude* to half of either parallelogram, say D B C A; and *p* (§ 18. § *a.*) is also the altitude of the triangle A H C.

§ *c. Cor.* If a triangle and a parallelogram have their bases and altitudes equal, the triangle is equal in magnitude to half the parallelogram.

§ *d. Cor.* Triangles which have the same or equal bases and altitudes, are of the same magnitude.

PROPOSITION XI.

§ 35. When two sides (A C and C B) of any triangle (A C B) are equal to two sides (E A and A C) of another (A E C), if the angles (A C B and C A E), which these sides contain, be equal, the two triangles are equal.



§ *a.* Let one of the equal sides (A C) be made common to the two triangles proposed, by constructing them on opposite sides of it; the figure A E C B, thus formed, will be a quadrilateral.

§ *b.* By the conditions of the proposition, the angle E A C = A C B, and they are alternate angles, made by A C with the equal lines E A and C B, therefore (§ 30.) E A and C B are parallel; and the opposite straight lines (E C and A B) which join their extremities are also parallel, wherefore (§ 30.) the alternate angles E C A and C A B are equal to each other.

§ *c.* E and B are the remaining angles of the two triangles, and (§ 32. § *e.*) they are equal to each other, for (§ *b.*) E A C + E C A = A C B + C A B, therefore the angles of the two triangles proposed are equal to each other.

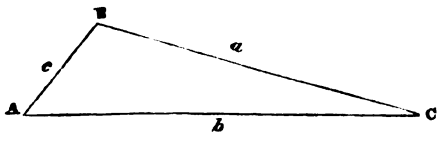
§ *d.* Now, since E A C + B A C = E C A + B C A the whole (§ 24 § *d.*) E A B is equal to the whole E C B; and (§ *c.*) E = B; these four are the opposite angles of the quadrilateral A E C B, which therefore (§ 33. § *g.*) is a parallelogram, and (§ 19.) E C = A B, and (§ 33.) A C divides the parallelogram into the two equal triangles A C B and A E C.

§ *e. Cor.* If the opposite sides of a quadrilateral figure be either parallel or equal, the figure is a parallelogram.

PROPOSITION XII.

§ 36. Either side (*b*) of any triangle is less than the sum of the two other sides (*a* & *c.*)

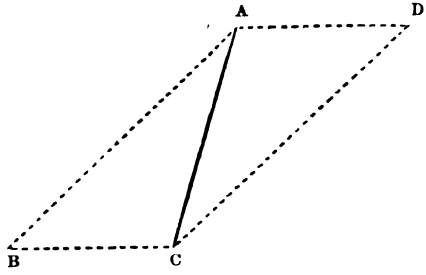
Digitized by Google



§ *a*. The straight line *b*, which joins the two points A and C, is less than the two straight lines *c* and *a* which join the same two points, because the shortest distance between any two points (A and C) (§ 3.) is the straight line (*b*) which joins them; wherefore *b* is less than the sum of the two other sides of the triangle, or of any two lines that can join A and C.

PROPOSITION XIII.

§ 37. Any two triangles (C A B and D C A) are equal, if a side (A C), and the two angles (B A C and B C A) adjacent to it, in the one, be respectively equal to a side (C A) and the two angles (A C D and C A D) adjacent to this side in the other.



§ *a*. Let the equal side (A C) be made common, by constructing the two proposed triangles upon it, so that one of them may be on each side of the common line A C; the figure (B A D C) thus formed is a quadrilateral, and the side A C, which is common to the two proposed triangles, is a diagonal of it.

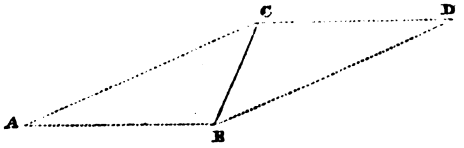
§ *b*. By the conditions of the proposition, the angles B A C and A C D are equal, and (§ 28. § *d*.) they are alternate angles, wherefore (§ 30 § *d*.) the two opposite sides (B A and C D) of the quadrilateral, are parallel. By supposition, also, B C A and C A D are equal, and they are likewise alternate angles, wherefore (§ 30. § *d*.) the other two opposite sides, (B C and A D) of the figure, are parallel.

§ *c*. If the opposite sides of a quadrilateral figure (§ 35. § *e*.) be parallel, the figure is a parallelogram; therefore B A D C is a parallelogram, and it is divided by the diagonal A C into the two proposed triangles C A B and D C A, which (§ 33.) are therefore equal to each other.

PROPOSITION XIV.

§ 38. Any triangles (B C A and D B C) are equal, if two angles (A and A B C) and an opposite side (C B), in one of the triangles be respectively equal to two angles (D and B C D) and the corresponding side (B C), of the other triangle.

Digitized by Google



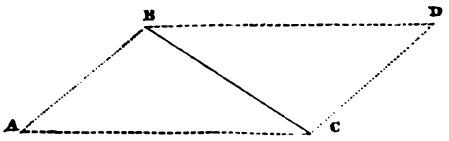
§ *a*. Let the equal side (C B) be made common to the two triangles, by constructing them so that one will be on each side of C B. Then C B becomes diagonal to the quadrilateral figure A C D B, which is formed by thus constructing the two proposed triangles.

§ *b*. By supposition, A = D, and A B C = B C D; wherefore (§ 32. § *e*.) the remaining angles A C B and C B D are equal to each other, and they are alternate angles, therefore (§ 30. § *d*.) the two opposite sides, C A and D B, of the four sided figure are parallel; the other two opposite sides, C D and A B, are also parallel, the alternate angles A B C and B C D being equal, by the conditions of the proposition. Therefore, the quadrilateral A C D B (§ 35. § *e*.) is a parallelogram, and is divided by the diagonal B C, (§ 33.) into the two equal triangles B C A and D B C.

§ *c*. *Cor*. Hence it is inferred, that if two angles and a side of one triangle be equal to two angles, and a side of another, the two triangles are equal.

PROPOSITION XV.

§ 39. Any two triangles (B A C and B D C) are equal, if every side of the former be equal to its corresponding side in the latter: *e. g*. A B = D C; A C = B D; and B C = C B.



§ *a*. Let one of the sides (B C) be made common to the two triangles proposed, by constructing one of them on each side of B C; the figure (A B D C) thus formed is a quadrilateral, and the common side B C is a diagonal of it.

§ *b*. By the conditions of the proposition A B is equal to D C, and A C to B D, and they are opposite sides of the quadrilateral figure A B D C; and if the opposite sides of a quadrilateral figure be equal (§ 35. § *e*.), the figure is a parallelogram; therefore A B D C is a parallelogram, and its diagonal B C divides it into the two proposed triangles B A C and B D C, which (§ 33.) are therefore equal.

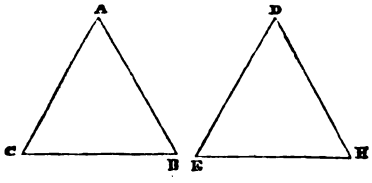
§ *c*. Scholium. Since the corresponding parts in equal figures (§ 23.) are equal, it follows:—

§ *d*. *Cor*. That if the sides of one triangle be equal to the sides of another triangle, the angles opposite the equal sides are equal.

PROPOSITION XVI.

§ 40. Every equilateral triangle (A B C) is also equiangular.

Digitized by Google



§ *a.* Let an equilateral triangle (E D H) be drawn, having its sides equal to those of the proposed triangle. The two triangles (§ 39.) are then equal, and the angles A and D which correspond, (§ 39. § *d.*) are equal to each other.

§ *b.* By the conditions of the proposition each side of A B C is equal to the same thing, and by construction, equal to either side of E D H; then A B = E H; and the two triangles (§ *a.*) being equal, the angles D and C, which are opposite to those equal sides (§ 39. § *d.*) are equal. Wherefore A and C are each equal to D, and, therefore, (§ 24. § *a.*) equal to each other. In the same manner B and A may be proven to be equal to each other. Wherefore C and B are each equal to A, and consequently the equilateral triangle A B C is equiangular.

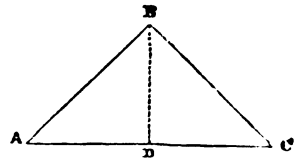
§ *c. Cor.* Every equiangular triangle is also equilateral.

§ *d.* Scholium. Since the three angles of any triangle (§ 32.) are together equal to 180°, and the three angles of an equilateral or equiangular triangle, are equal to each other:

§ *e. Cor.* Every angle in any equilateral or equiangular triangle, contains 60.°

PROPOSITION XVII.

§ 41. The angles (A and C) at the base of an isosceles triangle A B C (§ 14.), are equal to each other.



§ *a.* Let the base (A C) of the proposed triangle be divided into two equal parts (A D and D C) by a straight line (B D) drawn from the vertex (B) of the triangle.

§ *b.* This line (B D) divides the isosceles triangle into the two triangles A B D and D B C, in which every side of the one is equal to the side which corresponds to it in the other, viz: A B = C B (§ 14.) for they are the legs of the isosceles triangle A B C; A D = D C (§ *a.*), by construction; and B D is common to both of the triangles; therefore (§ 39.) these two triangles (A B D and D B C) are equal, and the corresponding angles A and C, being opposite to the common side B D, are therefore (§ 39. § *d.*) equal to each other.

§ *c.* Scholium. A B D = C B D, because (§ 39. § *d.*) they are opposite to the two equal sides A D and D C; for a similar reason B D A and B D C are also equal to each other, and (§ 25.) these are together equal to two right angles, therefore each of them is a right angle, and the right line B D (§ 6. § *b.*) is perpendicular to the base (A C) of the isosceles triangle A B C; wherefore:—

§ *d. Cor.* A straight line drawn from the vertex, so as to bisect the base of an isosceles triangle, is perpendicular to the base, and it divides

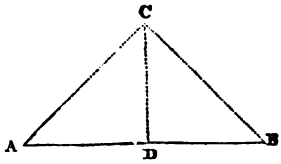
Digitized by Google

the vertical angle (A B C) into two equal parts, and the isosceles into two equal triangles. Also,

§ *e. Cor.* A straight line (B D) that is drawn perpendicularly from the vertex to the base of an isosceles triangle, bisects the vertical angle and the base.

PROPOSITION XVIII.

§ 42. If only two angles (A and B) of a triangle (A C B) be equal, the triangle is isosceles.



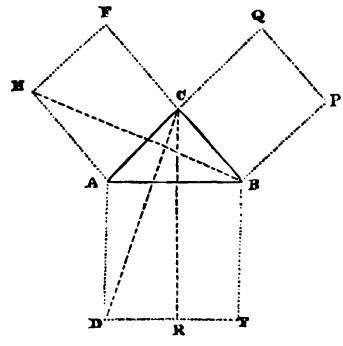
§ *a.* Call the other angle (C) (§ 16. § *b.*) the vertex of the proposed triangle; and from it, let the straight line C D be drawn, so as to bisect the vertical angle (C), and divide the proposed triangle into the two C A D and C B D, in which, by construction, the side C D is common, the angles A C D and B C D equal, and (§ 42.) A = B; wherefore in these two triangles (C A D and C B D), two angles and a side of the one are equal to the homologous angles and side of the other, and therefore (§ 38. § *c.*) these two triangles are equal to each other; consequently (§ 23.) the corresponding sides, C A and C B, are equal, and hence, (§ 14.) the triangle A C B is isosceles.

PROPOSITION XIX.

§ 43. In every right angled triangle (A C B), the square (D A B E) of the hypothenuse (§ 17. § *a.*) is equal in magnitude to the squares (A C F H and B C Q P) of the two legs.

§ *a.* Let D A B E represent the square (§ 20.) of the hypothenuse (A B), and A C F H and B C Q P, the squares of the two legs A C and B C; then (§ 43.) D A B E = A C F H + B C Q P.

§ *b.* From the right angle (A C B) let C R be drawn parallel to the parallels (§ 20. and § 19.) A D and B E, join C D and H B.



§ *c.* The angles of a square (§ 20. § *a.*) are right angles, and all right angles (§ 6. § *a.*) are equal, therefore H A C = D A B; to each of these equals add the angle B A C, and the sums H A B and D A C (§ 24. § *b.*) will be equal; also H A = A C, because (§ 20.) they are sides of the same square A F; and D A = A B, because they also are sides of a square A E.

§ *d.* Wherefore, in the two triangles A H B and A D C, the two sides H A and A B of the one, are respectively equal to the two sides C A and A D, of the other, and the angles H A B and D A C, con-

Digitized by Google

tained by these sides, are also equal (§ *c.*), therefore (§ 35.) the two triangles are equal.

§ *e.* The triangle A D C is equal in magnitude (§ 34.) to half of the parallelogram A R, for they stand upon the same base D A, and between the same parallels (§ *b.*) C R and A D. And the triangle A H B is equal in magnitude to half of the parallelogram A F, because they stand upon the same base A H, and between the same parallels H A and F C B.

§ *f.* The parallelograms A F and A R, being each double of either of the equal triangles (§ *d.*) A H B and A D C, are therefore (§ 24. § *b.*) equal to each other in magnitude; but the parallelogram A F (§ *a.*) is the square of the leg A C; wherefore the square of the leg A C, and the parallelogram A R, are of the same magnitude.

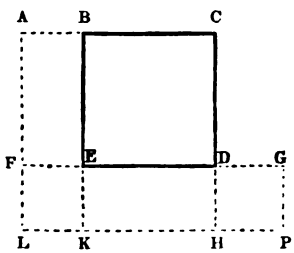
§ *g.* By joining A P and C E, it may be demonstrated in the same manner, that the parallelogram B R, and the square (B P Q C) of the other leg B C, are of the same magnitude.

§ *h.* The parallelograms A R and B R make up the square (D A B E) of the hypothenuse (§ *a.*) A B, therefore (§ 24. § *a.*) the square of the hypothenuse (A B) is equal in magnitude to the sum of the squares of the two legs (A C and C B).

PROPOSITION XX.

§ 44. The square described on the difference of two lines, is equal to the sum of the square of these two lines diminished by twice the rectangle under them.

§ *a.* Let A B, A C, be the two lines, and B C their difference. Then is B C^2 or $(A C - A B)^2 = 2 A C \times A B$.



§ *b.* Upon A C construct the square A C H L; through B, draw B K parallel to A L: upon H D taken as equal to A B, construct H D G P as the square of A B, and produce G D to F. B E D C thus becomes the square of B C; A L H C and H D G P the squares of the two lines A C and A B.

§ *c.* A L K B is a rectangle under A B and A C; so also is E K P G. Now if we take these two rectangles away from the square of A C and A B (§ *b.*) just described, it is clear that the square of B C only will remain.

GEOMETRY.

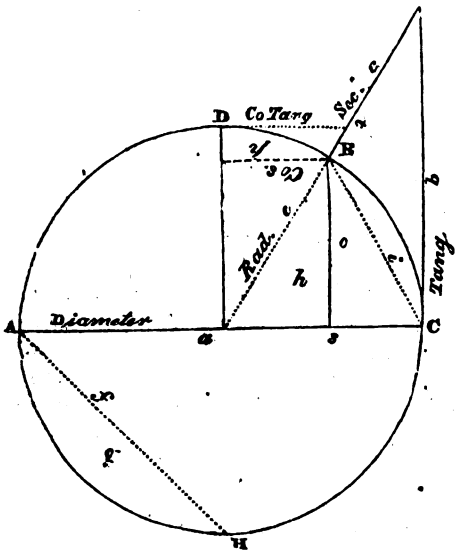
DEFINITIONS.



§ 49. *A circle* is a figure that is bounded by a line of uniform curvature: all parts of this line are equi-distant from a point (*a*) within it, which is called the *centre*.

§ *a*. If a straight line of any determinate length were to revolve in a plane, and on the point at one of its own extremities, its other extremity would describe the *circumference* (A D C H) of a circle; the point (*a*) on which the line would revolve, would be the *centre* of the circle; the length of the revolving line would be the *radius* (*a* B) of the circle; and the plane in which the line would revolve, would be the *plane* of the circle.

§ *b*. The circumference (A D C H) of every circle is divided into 360 equal parts, called degrees (°); every degree is divided into 60 equal parts, called minutes (′); every minute is divided into 60 equal parts, called seconds (″); and these, when calculations are performed in which great nicety is required, are divided into halves, tenths, or hundredths, the last marked thus (‴).

§ *c*. Whether the circumference of a circle be infinitely great, or infinitely small, a degree is still the same; and the circumference of the smallest is equal to the circumference of the largest circle, when the two circumferences are compared in degrees, minutes and seconds, to each other; for a degree is merely the 360th part of the circumference of its circle.

§ *d*. Degrees (°), minutes (′), and seconds (″), are the terms in which the value of angles is expressed.

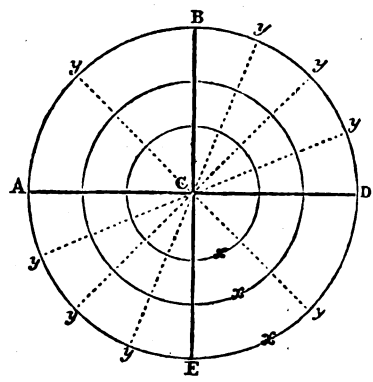
Digitized by Google

§ *e*. When the straight lines which contain an angle, are produced to the circumference of any circle that may be described from the angular point as a centre, that part of the circumference which the two lines intercept, contains the degrees, etc., which express the value of said angle. An angle is said to *stand* upon the part of the circumference that is thus intercepted. Neither the length of the lines which contain the angle, nor the distance of it from the circumference by which it is measured, affects its angular value.

§ 50. *The radius* of a circle is a straight line (*e*) that extends from the centre to the circumference of the circle.

§ *a*. All the radii of the same, or equal circles, are themselves equal.

§ *b*. If any number of straight lines, as B E, A D, *y y*, be supposed to cross each other at the same point C, and if, from this point as a centre, any number of circles, as *x*, *x*, *x*, be described, the circumference of each circle will be divided into as many parts—called arcs—as there are angles. All the angles at such a point (§ 26.) are together equal to four right angles of 90° each, which together are to 360°, or 90° × 4. And hence the circumference of every circle (§ 49. § *b*.) is divided into 360 equal parts called degrees.



§ *c*. Each angle, as B C *y*, (§ 49. § *e*.) and every arc it subtends, contains the same number of degrees and parts of a degree. Wherefore, the proportion of each of these arcs to the entire circumference of its circle, is the same. Moreover, their subtending angle has the same ratio to four right angles, that each of the arcs subtended has to its circle.

§ *d*. Therefore all arcs which contain the same number of degrees, and parts of a degree, are said to be similar.

§ *e*. Hence, too, when an arc is said to contain so many degrees, etc., no reference is had to the absolute length of the arc, but only to the ratio which the arc bears to the circumference of its circle. Thus, when we say that A B is an arc of 1°, we mean that A B is the 360th part of the circumference of its circle. But when we wish to determine the absolute length of an arc of any given number of degrees, we must first ascertain the distance of the arc from its centre, or which is the same thing, the absolute length of its radius; for (vide Proposition II. § 76. § *e*.) the circumferences of different circles, or of similar arcs, are to each other as their radii.

§ 51. *The diameter* of a circle is a straight line (A C) that passes through the centre of the circle, and is terminated at each end by the circumference of the circle.

Digitized by Google

§ *a*. Either of the two parts (fig. § 49.) (A D C & A H C) into which the diameter divides the circle, is a *semicircle*.

§ *b*. *A segment* of a circle is any part (*g*) cut from the circle by a line (*f*), or a plane, which crosses the circle.

§ 52. *An arc* of a circle is any part of its circumference. That part (A H) of the circumference which bounds a segment (*g*) is an arc; and the straight line (*f*) which joins the extremities of an arc, is a chord.

§ *a*. The *complement* of an arc, or angle, is the difference between either and 90°; and the *supplement* is what either wants of being 180°.

§ *b*. The radius and centre of a segment, or of an arc, are the radius and centre of the circle, of which the segment, or the arc, is a part.

§ *c*. Every arc or angle has its sine and co-sine, tangent and co-tangent, secant and co-secant, besides its versed sine and semi-tangent.

§ *d*. The "*co*" is an abbreviation for *complement:* the co-sine, co-tangent, etc., of an angle or an arc, are the sine, tangent, etc., of the *complement* of that arc or angle.

§ *e*. The sine, tangent, secant, etc., of an arc, are also the sine, tangent, secant, etc., of the supplement of that arc.

§ 53. *A chord* is a straight line (*i*) (§ 52.) that joins the extremities of an arc (B C).

§ *a*. Every arc has its chord.

§ *b*. When a chord passes through the centre of a circle, it becomes a diameter, and the arc it subtends is a semicircle.

§ 54. *A sine* is a straight line (*o*) that extends from one extremity (B) of an arc (B C) perpendicularly to the radius (*a* C) that joins the other extremity.

§ 55. *A versed sine* is that part (*s* C) of the radius which is intercepted between the sine and the extremity of the arc.

§ 56. *A tangent* is a line (*b*) that touches one extremity of an arc (B C), is perpendicular to the radius (*a* C) at that extremity, and extends to another radius (*e*) produced through (B) the other extremity of the arc.

§ 57. *A secant* (*a* B *c*) is the produced radius (*e*) that intersects the tangent.

§ *a*. The co-sine, co-tangent, and co-secant of the arc B C, are *p*, D *t*, and *a t*; and *p* (§ 19.) is equal to *a s*.

§ *b*. The sine, co-sine, tangent, co-tangent, etc., of an angle, are the sine, co-sine, tangent, co-tangent, etc., of the arc which subtends that angle.

§ *c*. All of which are sometimes called *trigonometric functions*.

§ 58. *A sector* is a figure (*h*) contained by two radii (*a* B, *a* C), and the arc (B C) between them.

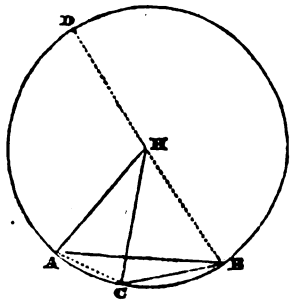
PROPOSITION I.

§ 59. An angle (A B C) at the circumference, is equal to half of an angle (A H C) at the centre, if they stand upon the same arc (C A), of a circle.

§ *a*. Draw the chord A C, and from B let a diameter (B H D) be

Digitized by Google

drawn. The radii H A, H C, and H B (§ 50. § *a.*) are equal, and the triangles A H B and C H B (§ 14.) are isosceles. The exterior angle C H D (§ 31.) is equal to the two interior angles (H B C and H C B) of the triangle C H B; for the same reason the exterior angle (A H D) of the triangle A H B, is equal to its two interior angles H A B and H B A, which are equal to each other, because (§ 41.) they are at the base of the isosceles triangle A H B; therefore A H D is double of either of them, say of H B A. For the same reason H B C and H C B are equal to each other, and C H D is double of either, say of H B C.



The difference between C H D and A H D, is C H A, and the difference between their equals, viz., twice H B C and twice H B A, is twice A B C. Wherefore C H A (§ 24. § *b.*) is equal to twice A B C; or, which is the same thing, the angle (A B C) at the circumference, is equal to half of the angle A H C at the centre of a circle, and both of them stand upon the same base.

§ *b.* An angle at the centre of a circle, is measured (§ 49. § *e.*) by the arc it stands upon; Wherefore—

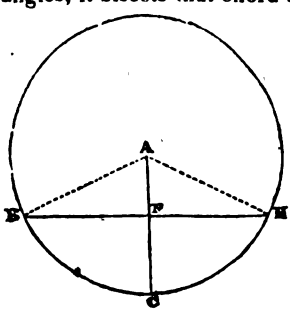
§ *c. Cor.* An angle at the circumference of a circle is measured by half the arc which subtends it.

§ *d. Cor.* All angles are equal that are at the centre, or all angles are equal that are at the circumference, if they stand upon the same, or equal arcs.

§ *e. Cor.* An angle that is at the circumference, and that stands upon a semicircle (§ *c.*), is a right angle.

PROPOSITION II.

§ 60. If the radius (A C) of a circle, cut a chord (B H) at right angles, it bisects that chord and its arc (B C H).



§ *a.* Let the radii, A B and A H, be drawn to join two extremities of the chord (B H). The triangle (B A H) thus formed (§ 50. § *a.* and § 14.) is isosceles. And the straight line A F C bisects the vertical angle H A B (§ 41. § *e.*); for by the conditions of the proposition, A C is perpendicular to the chord B H, which is the base of the isosceles triangle B A H. Wherefore (§ 41. § *d.*) the two triangles B F A and H F A are equal, B H is bisected, and the angles B A C and H A C are equal to each other, and being equal (§ 59. § *d.*) they stand upon equal arcs (B C and C H). Therefore the chord (B H), and its arc (B C H), are bisected by the radius A C.

Digitized by Google

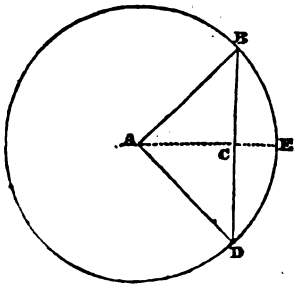
§ *b. Cor.* If a radius bisect an arc, it also bisects the chord of that arc, and cuts the chord at right angles.

§ *c. Cor.* If a radius bisect a chord, it also bisects the arc of that chord, and cuts the chord perpendicularly.

§ *d. Cor.* If a radius bisect a chord, or its arc, it also bisects the angle at the centre, which stands upon that arc.

PROPOSITION III.

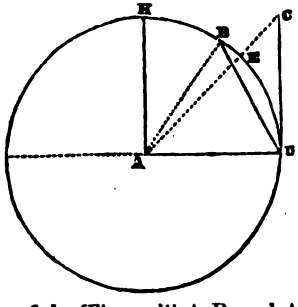
§ 61. B C, half the chord (B D) of an arc (B E D), is the sine of C A B, half the angle (D A B) which that arc subtends.



§ *a.* Let the chord be bisected at C, and through C let the radius A C E be drawn, then this radius (§ 60. § *c.*) bisects the arc B E D, cuts the chord B D at right angles, and also (§ 60. § *d.*) bisects the angle (D A B) which this arc subtends. Wherefore, B A C is half of the angle D A B, B C is half the chord of B E D, and it is perpendicular to the radius A C E; therefore (§ 54.) B C, half the chord of B E D, is the sine of C A B, which is half of the angle (D A B) proposed.

PROPOSITION IV.

§ 62. In any circle, radius (A D), the sine (A H) of 90°, the chord (B D) of 60°, and the tangent (D C) of 45°, are all equal to each other.



§ *a.* Let A be the centre of the circle, the arc H B E D = 90°, the arc B E D = 60°, and the arc E D = 45°; then join B A and C A. The angles at the centre (A) (§ 49. § *e.*) are measured by the arcs they stand upon; therefore the angle D A C = 45°, D A B = 60°, and D A H = 90°; A H then (§ 6. § *b.*) is perpendicular to A D, and A H (§ 54.) is the sine of the arc H B E D = 90°, it is a radius, and therefore (§ 50. § *a.*) equal to A D.

§ *b.* The radii A B and A D being equal (§ 50. § *a.*), makes the triangle B A D (§ 14.) isosceles; consequently (§ 41.) the angles A B D and A D B are equal. The angle D A B = 60° (§ 49. § *e.*) because it stands upon the arc B E D; wherefore (§ 32.) A B D + A D B = 120°, and being equal, the value of each is 60°; therefore the triangle B A D is equiangular, and (§ 40. § *c.*) also equilateral; consequently (§ 13.) the chord (B D) of 60° is equal to radius (A D).

§ *c.* C D is the tangent of E D = 45°, and consequently (§ 56.) is

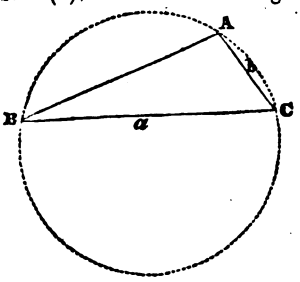
Digitized by Google

perpendicular to A D; wherefore (§ 6. § *b*. & § *a*.) the angle C D A = 90°, and (§ 17.) the triangle A D C is right angled. The angle C A D = 45° (§ 49. § *e*.), because it stands upon the arc E D, therefore (§ 32. § *d*.) the angle A C D is also equal to 45°, and is equal to C A D, and (§ 42.) the triangle A D C is isosceles, and (§ 14.) the tangent (D C) of 45° is equal to radius (A D).

§ *d*. Therefore the tangent of 45° (§ *c*.), the chord of 60° (§ *b*.), and the sine of 90° (§ *a*) being each equal to radius, are (§ 24. § *a*.) equal to each other.

PROPOSITION V.

§ 63. In every triangle, the angle (A) that is opposite to the greatest side (*a*) is the largest, and (B), that which is opposite to the smallest side (*b*), is the smallest angle of the triangle.



§ *a*. Describe a circle (A C H B) about the proposed triangle B A C, the circumference of which touches the three angular points (B, A, and C) of the triangle. Each side of the triangle then becomes the chord to the arc, which subtends the angle that is opposite to it.

§ *b*. The angle A stands upon the arc B H C, which is greater than either of the arcs (B A, A C) upon which the two other angles (C and B) of the triangle stand. Each of these three angles (§ 59. § *c*.) is measured by half the arc that subtends it. Therefore A, which stands upon the greatest arc, and subtends the greatest side (*a*), is the largest angle of the proposed triangle.

§ *c*. Half the smallest arc (A C) (§ 59. § *c*.) measures the angle (B) that stands upon it; therefore B (the angle that is opposite to the smallest side) (*b*) is the smallest angle of the triangle.

DEFINITIONS.

§ 64. The *multiple* of a magnitude is the product of this magnitude and any other factor.

§ *a*. *Equimultiples* of magnitudes are the product of each of these magnitudes by the same or equal multipliers.

§ *b*. Thus, 15 and 30 are equimultiples of 3 and 6; for $3 \times 5 = 15$, and $6 \times 5 = 30$. Consequently (§ 24. § *b*.)—

§ 65. The same or equal multiples of equal magnitudes are equal to each other.

§ 66. *Ratio* is the relation which the value of any magnitude bears to that of another, and it is shown by dividing one magnitude by the other.

§ *a*. Thus, the ratio of *a* to *b* is $a \div b$, and is expressed thus,—$a : b$.

Digitized by Google

§ *b.* And if the ratio between two quantities (*a* & *b*) be equal to the ratio between two other quantities (*c* & *d*), this equality of ratio is expressed (§ XLV. Algebra) by writing the sign (: :) between the two former and the two latter quantities, thus,—*a* : *b* : : *c* : *d*.

§ 67. *Proportion* consists in the equality of the ratios between magnitudes.

§ *a.* Thus, the ratio (§ 66.) of 3 to 4 is $\frac{3}{4}$; and the ratio of 6 to 8 is $\frac{6}{8}=\frac{3}{4}$; and these quantities are proportional; *i. e.*, 3 : 4 : : 6 : 8.

§ *b.* Four quantities are in *direct* proportion, when the 4th is equal to the quotient, which arises from dividing by the 1st quantity, the product of the 2d and 3d. Thus (3 : 4 : : 6 : 8), $4 \times 6 = 24$; and $24 \div 3 = 8$. So, also, *a* : *b* : : *c* : *d*, which in Algebra (§ XLV.) is but another form for expressing that $a \div b = c \div d$; and by transposition $a \times d = c \times b$; also, $(c \times b) \div a = d$.

§ *c.* The first and third (*a* & *c*) of four magnitudes that are in direct proportion, are called *antecedents;* and the second and fourth (*b* & *d*) are called *consequents.*

§ *d.* Also the first and fourth (*a* & *d*) are called *extremes;* and the second and third (*b* & *c*) are called *means.*

§ *e.* It is a rule in proportion, that the quantities for calculation be so arranged that the product of the two extremes be equal to the product of the two means. Thus, $a \times d = b \times c$; and as $a \times d = d \times a$, (§ XXV. †1. Algebra), $d \times a = c \times b$. Wherefore the means may be made extremes, and the extremes means; as, *b* : *a* : : *d* : *c* (§ XLVIII. Alg.); the antecedents may be made consequents and the consequents antecedents; as, *d* : *c* : : *b* : *a*, without interrupting the harmony of the proportion between the quantities.

§ *f.* Hence if the value of three magnitudes be known, the unknown value of the fourth, which is in the same ratio of proportion, is determinable. It is the quotient that arises (§ *b.*) from dividing the product of the two means by the known extreme. Thus, 3 : 4 : : 6 : —; (a 4th quantity,) $4 \times 6 = 24$, and $24 \div 3 = 8$, the 4th quantity. Generally speaking, the magnitude whose value is required, is expressed last in the order of proportion.

AXIOMS.

§ 69. Among quantities that are proportional, equals may be substituted for equals.

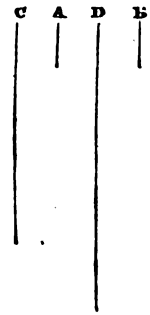
§ *a.* Magnitudes that are proportional to the same two, or to other magnitudes equal to these, are proportional to each other.

§ *b.* Equal magnitudes have the same ratio to the same magnitudes.

PROPOSITION VI.

§ 70. The same, or equimultiples (C and D), of any two magnitudes (A and B), are to each other as the magnitudes themselves.

Digitized by Google



§ *a*. Let C be the same multiple, say the 5th, of A, that D is of B; then (§ 64. § *a*.) A × 5 = C, and B × 5 = D; by transposition C ÷ A = 5, and D ÷ B = 5; wherefore (§ 24. § *a*.) C ÷ A = D ÷ B; then (§ XLVI.) C : A : : D : B, and alternately (§ XLVIII.) C : D : : A : B. Therefore, the equal multiples are as the magnitudes.

§ *b*. Scholium. The magnitude of a triangle (§ 33. § *c*.) is the product of its base and half of its altitude.

§ *c*. Wherefore the magnitudes of triangles of the same altitude, are equimultiples of their bases. And so of parallelograms of equal altitudes; and therefore,

§ *d*. *Cor*. Triangles, or parallelograms, that have the same altitude, are, in magnitude to each other as their bases; or those that have equal bases are to each other as their altitudes.

PROPOSITION VII.

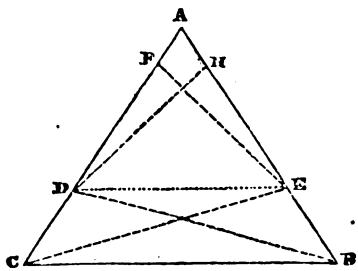
§ 71. When the product of any two quantities (*a* & *b*) equals the product of two others (*c* & *d*), the ratio of the greater multiplicand to the greater multiplier, is equal the ratio of the less multiplicand to the less multiplier; and the four quantities are proportional.

§ *a*. Let $a \times b = c \times d$ be the four quantities proposed, and let *a* be the greater multiplicand, then *d* will be the greater multiplier, *b* the less, and *c* the less multiplicand; and (§ 71.) $a : d : : c : b$.

§ *b*. By the conditions of the proposition $a \times b = c \times d$, and by transposition (§ XLII.) $a \div d = c \div b$; or $d \div a = b \div c$; therefore these quantities (§ XLV.) are proportional; *i. e.*, $a : d : : c : b$, or $d : a : : b : c$, and consequently (§ 67. § *a*.) their ratios are the same.

PROPOSITION VIII.

§ 72. If a straight line (D E) be drawn parallel to the base (C B) (§ 16. § *b*.), and so as to cut the two sides (A C and A B) of any triangle (A B C), the sections (A D, D C, A E, & E B) of these two sides will be proportional; *i. e.*, A D : D C : : A E : E B.



§ *a*. Join D B and C E; and let E F be drawn from the vertex (E) of the two triangles A E D and C E D, perpendicularly upon A C, then (§ 18. § *a*.) E F is the altitude of each of these two triangles. In the same manner, by drawing D H perpendicular to A B, it is shown that the two triangles A D E and B D E have the same altitude (D H).

§ *b*. The triangles A E D and C E D, having the same altitude (E F), are to each other (§ 70. § *d*.) as their bases; *i. e.*, A E D : C E D

Digitized by Google

: : A D : D C. And the triangles A D E and B D E are to each other also as their bases; *i. e.*, A D E : B D E : : A E : E B.

§ *c.* The triangle A D E is a magnitude in each set of these proportions; and the triangles C E D and B D E are of the same magnitude (§ 34. § *d.*), for they stand upon the same base (D E), and between the same parallels (§ 72.) D E and C B.

§ *d.* Wherefore A D and D C, A E and E B, are proportional to the same or equal magnitudes; they are therefore (§ 69. § *a.*) proportional to each other; *i. e.*, A D : D C : : A E : E B.

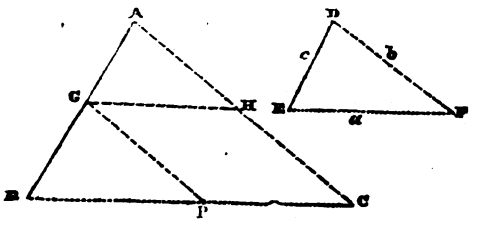
§ *e.* By drawing a straight line from the vertex B, perpendicularly upon A C, as a base; and another from C as a vertex, perpendicularly upon A B, it may be proved in the same way, that A C : D C : : A B : E B. And also that A C : A D : : A B : A E. Wherefore,—

§ *f.* *Cor.* If the two sides of a triangle be crossed by a line that is parallel to the base, these two sides will be proportional to their sections.

PROPOSITION IX.

§ 73. The homologous sides (§ 23 § *c.*) of similar triangles (A B C and D E F) are proportional to each other, viz., A B : *c* : : A C : *b* : : C B : *a*.

§ *a.* By the conditions of the proposition, the triangles A B C and D E F are similar, wherefore (§ 23. § *b.*) their corresponding angles are equal, viz., B = E, A = D, and C = F. Upon the two sides A B and A C of the greater triangle, (A B C) let A G be set off, equal to *c*, and A H = *b*; let G H be joined, then (§ 35.) the two triangles A G H and D E F are equal to each other; therefore (§ 23.) G H = *a*, the angle A G H = E, etc.



§ *b.* The angle A G H (§ *a.*) = E, and B = E, therefore (§ 42, § *a.*) A G H = B, and (§ 30. § *d.*) G H is parallel to B C. Consequently (§ 72. § *f.*) A B : A G : : A C : A H; by construction A G = *c*, and A H = *b*; then substituting for A G and A H their equals, we have (§ 69.) the proportion A B : *c* : : A C : *b*.

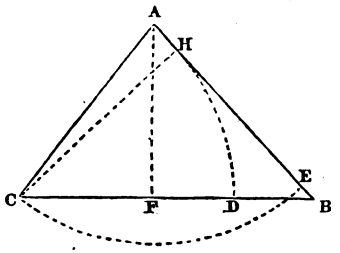
§ *c.* Then by drawing from G, G P parallel to A C, the parallelogram G P C H (§ 35. § *e.*) is formed; and (§ 72. § *f.*) we have A B : A G : : C B : C P. But (§ 19.) C P = G H, and (§ *a.*) G H = *a*; also A G = *c*. Therefore (§ 69.) A B : *c* : : C B : *a*.

§ *d.* *Cor.* Whence it may be inferred, that if a straight line be within a triangle and parallel to its base, the ratio of the base to this line will be equal to the ratio of the sides to their sections.

PROPOSITION X.

§ 74. In every triangle (A B C) the sides are proportional to the sines of their opposite angles.

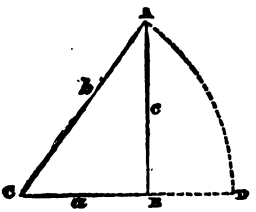
Digitized by Google



§ *a.* From C and A, as centres, and with A C as the radius, let the arcs A D and C E be described, and draw A F perpendicular upon B C, and C H perpendicular upon A B; then (§ 54.) A F is the sine of the angle A C B, and C H is the sine of the angle C A B.

§ *b.* Of the two triangles B H C and B A F, the angle at B is common, the right-angles A F B and C H B are equal, wherefore (§ 32. § *e.*) the remaining angles H C B and F A B are equal, and (§ 23. § *b.*) these two triangles are similar.

§ *c.* The homologous sides of similar triangles (§ 73.) are proportional; wherefore A B : C B : : A F : C H; and A F and C H (§ *a.*) are the sines of the angles A C B and C A B; therefore A B : C B : : sine A C B : sine C A B. In the same manner it may be proved that A C : C B : : sine A B C : sine C A B.

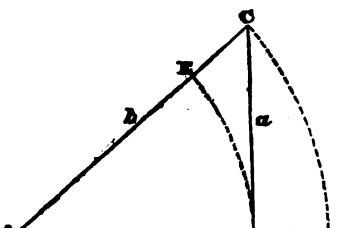


§ *d.* If the proposed triangle be right angled, and the hypothenuse be made radius, the hypothenuse becomes (§ 62. § *a.*) the sine of the right angle, and the legs (*c* and *a*) the sines of their opposite angles (C and A), whence we have a self-evident truth, viz., A B : C B : : *c* : *a*; but *c* and *a* are the sines of C and A, therefore A B : C B : : sine C : sine A. Also A C : A B : : *b* : *c*; but *b* is the sine of B, and *c* sine of C, therefore A C : A B : : sine B : sine C; and (§ 62.) the sine of B is equal to radius. By like reasoning, it is shown that A C : C B : : sine B : sine A. Wherefore,

§ *e. Cor.* If an hypothenuse be made radius, that hypothenuse is to either leg as radius is to the sine of the angle opposite that leg.

PROPOSITION XI.

§ 75. In every right angled triangle, the sides are proportional to the several *trigonometric functions* (§ 57. § *c.*) of the two acute angles.



§ *a.* Let the hypothenuse (*b*) of the proposed triangle, be made radius (A C) to an arc C D = A. Then (§ 54. and § 57. § *a.*) C B is the sine, and A B the co-sine of A; likewise A B is the sine, and C B the co-sine of C.

§ *b.* Now (§ XXV. †1.) $b \times a = C B \times A C$; then (§ 71.) *b* : A C : : C B : *a*; by construction (§ *a.*) A C is radius, and C B is sine A or co-sine C; therefore *b* : Radius : : sine A or co-sine C : *a*. Again, $b \times c = A B \times A C$, and A B (§ *a.*) is the co-sine of A, and sine of C; therefore, *b* : Radius : : co-sine A or

Digitized by Google

sine C : *c*. And these quantities (§ XLVII.) are also proportional, when taken inversely or alternately.

§ *c*. Let either of the legs (*c*) be made radius (A B) to another arc E B = A. Then C B becomes tangent (§ 56.) to A, and (§ 57. § *b*.) co-tangent to C; and A C (§ 57.) the sec. of A, and co-sec. of C. And (§ XXV. †1.),

1st. A B × *a* = C B × *c*, and (§ 71.) A B : *c* : : C B : *a*.
2d. A B × *b* = A C × *c*, " A B : *c* : : A C : *b*.
3d. A C × *a* = C B × *b*, " A C : *b* : : C B : *a*.

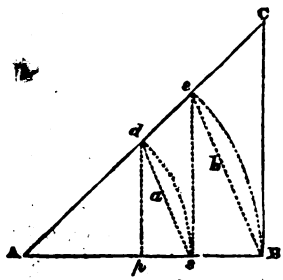
Now (§ *c*.) A B is radius, C B is tangent A, or co-tangent C, and A C is sec. A, or co-sec. C. Therefore in these three sets of proportions, the first is: Radius : *c* : : tangent A, or co-tangent C : *a*. The second is: Radius : *c* : : sec. A, or co-sec. C : *b*. And the third is: sec. A, or co-sec. C : *b* : : tangent A, or co-tangent C : *a*. And (§ XLVIII.) these quantities are also proportional, when taken inversely, or alternately.

§ *d*. If B C be made radius, the same method of demonstration will show that radius, the tangent and secant of C, and of its complement, are proportional to the sides (*a*, *b* and *c*) of the proposed triangle.

§ *e*. This proposition may be said to include Proposition X, (§ 74.) and to form the ground-work of Plane Trigonometry. See the numerous and valuable formulæ that are derived from it, under § 98. § 105. § 106. § 107, etc.

PROPOSITION XII.

The chords (*a* and *b*), sines (*d p* and *e s*), tangents *e s* and B C of similar arcs (§ 50. § *c*.) as *d s* and *e* B, are to each other as the radius A *s* of one of the arcs is to the radius A B of the other.



§ *a*. The proposed arcs (*d s* and *e* B) are concentric; *e s* is the tangent of *d s*, and C B of *e* B; by the definition of a tangent (§ 56.), these tangs. are perpendicular to A B; they are therefore parallel; and (§ 73. § *d*.) *s e* : B C : : radius A *s* : radius A B.

§ *b*. The sines (*d p* and *e s*) of these two arcs, are also parallel, and by the same proposition (§ 73. § *d*.) *d p* : *e s* : : A *s* : A B.

§ *c*. The chords *a* and *b*, are also parallel, and, for the reason above, are to each other as, A *s* : A B.

§ *d*. By similar methods of demonstration the secants, co-secants, co-sines, co-tangents, etc., of the two arcs, may be proved to have the same proportion to each other, which the two radii A *s* and A B have.

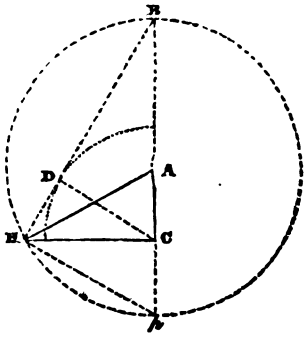
§ *e*. Hence also it follows that the lengths of radii of different arcs or circles, are to each other as the arcs or circles themselves; and conversely. But in speaking of the *length* of a radius, it should be borne in mind, that every radius bears the same ratio to the circumference of its circle—that is, that it is contained so many times in the circumfer-

Digitized by Google

ence, and that therefore the ratio between the circumference of every circle and its radius, is a constant ratio.

PROPOSITION XIII.

§ 77. The sum (B C) of two sides (C A and A H) of any triangle (A C H), is to the tangent of half the sum of their adjacent angles (H and C), as the difference (C p) between the same two sides, is to the tangent of half the difference between the same two angles; or B C : tangent $\frac{1}{2}$ (A C H + A H C) : : C p : tangent $\frac{1}{2}$ (A C H ∽ A H C).



§ *a*. With the greatest side (A H) of the proposed triangle, as radius, describe the circle B H p, about the centre A. The side A C is extended both ways, until it forms the diameter (B p) of the circle. Join B H, H p. D C is drawn parallel to H P.

§ *b*. Because A H = A B (§ 50. § *a*.); C A + A B, or C B is the sum of the two sides C A and A H. And because A H = A p; A p — A C, or C p is the difference between the same two sides.

§ *c*. The angle B H p (§ 59. § *e*.) is a right angle; then C D is perpendicular to B H, for it is drawn parallel to H p; therefore (§ 30.) C D B is a right angle; and B D is tang. of B C D.

§ *d*. The exterior angle H A B (§ 31.) is equal to the sum of the adjacent angles (A C H and A H C); H p B (§ 59.) is equal to half of H A B, for they stand upon the same arc (B H); then (§ 24. § *a*.) H p B = $\frac{\text{A C H + A H C}}{2}$. Because D C and H p (§ *a*.) are parallel, B C D (§ 28.) is equal to H p B; therefore B C D is equal to half the sum of the two angles A C H and A H C. And in the right angled triangle B D C, C B is the sum (§ *b*.) of the two sides A H, A C of the proposed triangle A C H, and B D (§ *c*.) is the tangent of B C D, which is half the sum of A C H and A H C.

§ *e*. By § 31, the angle A C H = C p H + C H p. Because A H = A p (§ 50. § *a*.), the triangle H A p (§ 14.) is isosceles; and (§ 41.) C p H = A H p. Then (§ 24. § *a*.) A C H = A H p + C H p; from this sum, subtracting A H C, the remainder is twice C H p, which is the difference between the two angles A C H and A H C; then C H p is *half* this difference. And (§ 29.) C H p = H C D; therefore H C D is half the difference between the angles A C H and A H C. Then making C D radius, D H (§ 56.) becomes tangent of H C D.

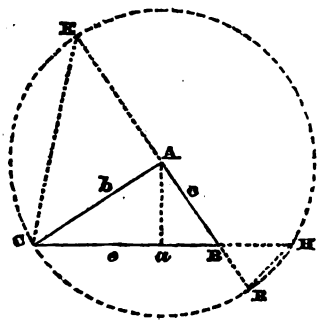
§ *f*. Now C p being the difference (§ *b*.) between the two sides A H and A C; and D C being parallel (§ *a*.) to the side H p of the triangle H B p; we have (§ 72.) B C : B D : : C p : D H. Or, C A + A H: tangent $\frac{\text{A H C + A C H}}{2}$: : C A ∽ A H : tangent $\frac{\text{A H C ∽ A C H}}{2}$.

Digitized by Google

§ *g*. Scholium. The half sum (§ *d*.) B C D added to the half difference H C D (§ *e*.) makes the greater angle A C H; and the half difference C H *p* (§ *e*.) subtracted from the half sum A H *p* (§ *e*.), gives the less angle A H C. Wherefore,

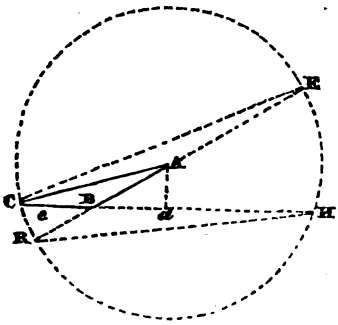
§ *h*. *Cor*. The half sum and half difference of any two magnitudes being known, the magnitudes themselves are also known.

PROPOSITION XIV.



§ 79. The base (*e*) of any triangle (A B C) is to the difference between the two sides (*b* and *c*), as their sum is to twice the distance from the middle of the base to a perpendicular (A *a*) falling upon the base from its opposite angle (A); that is, $e : b \sim c :: b + c$ is to twice the distance of *a* from the middle of the base.

§ *a*. With a radius equal to the longer side (*b*) of the proposed triangle, the circle E C R H is described about the angle (A) that is opposite to the base. Then *b* (§ 50. § *a*.) is equal both to A E and to A R; and the difference between the two sides *b* and *c* is (A R — *c* =) B R; and their sum is (*c* + A E =) B E;



§ *b*. Because the perpendicular A *a* is drawn from the centre of the circle upon the chord C H (§ 60.), it bisects it. Then the distance of the perpendicular at *a* from the middle of the base (*e*), *plus*, half the base, makes up (C *a*) half the chord C H. Double this, and we have the whole chord C H, which is made up of twice the distance from *a* to the middle of the base, and twice the half of the base *e*. Twice the half, is equal to the whole base *e*. Therefore subtracting the base *e* from the chord C H, the remainder (B H) is twice the distance of the perpendicular at *a* from the middle of the base.

§ *c*. The two sides C B, B E of the triangle E B C, are the base (*e*), and the sum of the two sides (*b* and *c*) of the proposed triangle. And the two sides B R, B H of the triangle H B R, make the difference between those sides (*b* and *c*,) and twice the distance (§ *b*.) from the perpendicular to the middle of the base (*e*). These two triangles (E B C and H B R) (§ 23. § *b*.) are similar; for the vertical angles E B C and H B R (§ 27.) are equal; and H C E = H R E (§ 59. § *d*.), they stand upon the same arc (H E); and the remaining angles C E R, C H R, (§ 32. § *e*.) are equal. Therefore (§ 73.) the homologous sides of

Digitized by Google

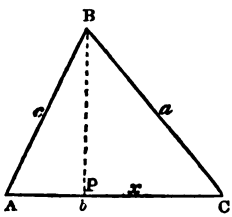
these two similar triangles are proportional; that is, C B : B R : : B E : B H; or $e : b \sim c : : b + c$: twice the distance of the perpendicular at a from the middle of the base.

§ *d.* Scholium. Then if the distance of the perpendicular from the middle of the base be added to *half* the base, the sum will be the greater segment (C a); or, if it be subtracted, the difference will be the smaller segment (B a) (§ 77. § *h.*)

§ *e.* C a and B a are called the segments of the base C B. Wherefore the segments of the side called the base, upon which the perpendicular falls, are measured by the distance of the perpendicular from each of the two angles, as B and C, adjacent to the base.

PROPOSITION XV.

§ 80. The square of any side of a triangle is equal to the sum of the squares of the other two sides diminished by twice the rectangle under them multiplied by the cosine of their included angle.*



§ *a.* Let A B C be the angles, and a b c be their opposite sides in the triangle A B C. From B let fall the perpendicular B P, and let x be the segment (§ 79. § *e.*) of the side b, between the perpendicular P and the angle C.

§ *b.* Now, taking a as rad. unity or 1, (which is fully explained under § 98), and considering (§ 75.) that x is cos. C, we have $x = 1$ cos. C, or $x = a$ cos. C.

§ *c.* Also, (§ 43.) $c^2 = P^2 + (b - x)^2$, and likewise (§ 44.) $c^2 = P^2 + b^2 + x^2 - 2\,b\,x$.

§ *d.* But, (§ 43.) $P^2 + x^2 = a^2$.

§ *e.* Substituting, therefore, a^2 for $P^2 + x^2$, and (§ *b.*) a cos. C for x in the latter equation (§ *c.*), we have $c^2 = a^2 + b^2 - 2\,a\,b$ cos. C.

LOGARITHMS.

§ 83. The purpose of logarithms is to facilitate arithmetical calculations. The term is derived from two Greek words (*logos* and *arithmos*), and may rightly be called the language of numbers; for by means of logarithms, not only multiplication and division, but involution and evolution, or the tedious operations of raising powers, and of extracting roots, are performed by the simple process of addition or subtraction. Thus, suppose two sides a and b of a triangle, and an opposite angle B be given, to find the value of the other opposite angle A. Let side

$$a = 2310.15 \text{ feet}$$
$$b = 2572.51 \text{ do.}$$
$$B = 37^\circ\ 14'\ 34''.\ 19'''$$

§ *a* These data (§ 74.) give the formula: sine $A = \frac{a}{b}$ sine B; which, substituting the values themselves for the letters, becomes sine $A = \frac{2310.15}{2572.51} \times$ sine $(37^\circ\ 14'\ 34''.\ 19''')$. The value of sine $(37^\circ\ 14'\ 34''.\ 19''')$ being taken from the proper tables, must be multiplied by 2310.15, and the product divided by 2572.51 for the answer. But with the aid of logarithms, the result is obtained by adding the Log. value of 2310.15 to the Log. sine of $37^\circ\ 14'\ 34''.\ 19'''$, and subtracting from this sum the Log. value of 2572.51.

§ *b*. When roots are to be extracted, or powers obtained, the first process indicated above becomes still more complex and tedious, and the practical advantages of the latter method are made more obvious.

§ *c*. The common rules of algebra for involution, evolution, etc., form the basis of this method; for, in logarithms all numbers are considered as powers of some other number arbitrarily assumed, and called the *base;* and the exponent (§ XII. § *a*.) of that power of the base which is equal to the number proposed, is called the logarithm of that number. Thus, if all numbers be considered as powers of 1. or 10., as in table 1, the Log. of 10^2 or 100, is 2; 2 being the exponent (§ XII. § *a*.) of 10^2: the Log. of 10^3, or 1000, is 3; 3 being the exponent of 10^3, and so on of 10^4 or 10000, etc.

§ *c*. If the logarithms that correspond to a series of numbers in geometrical progression, be taken out and noted down, they will be found to constitute another series of numbers in arithmetical progression. And if two series of numbers be arranged, one in the order of geometrical progression (the first term of which shall be unity or 1, and the common ratio 10), and the other in the order of arithmetical progression (the first term of which shall be zero (0), and the common difference 1), these two series will constitute a basis, or the ground-

Digitized by Google

work for forming a table of logarithmic numbers, like those most generally used.

§ *d.* By arranging the two series of numbers, the one in geometrical, the other in arithmetical order of progression, thus,

Geometrical progression.	Arithmetical progression.
1	0
10	1
100	2
1000	3
10000	4
100000	5
1000000	6
10000000	7
100000000	8
1000000000	9
10000000000	10,

the relation and connection between the orders of the two series will appear. The terms in the order of arithmetical progression, are the logarithms of those in the geometrical order: each the logarithm of the term to which it is opposite; *i. e.*, 0 is the logarithm of 1; the logarithm of 10 is 1, of 100 is 2, of 1000 is 3, of 10,000 is 4, and of 100,000 it is 5, etc.

§ *e.* By observing the different relations which exist between the terms in the two series above, it appears,—

1st. That the logarithm of any whole number has for its index the figure which expresses the number of digits, *minus one*, that are in the natural number for which the logarithm is required. Thus 1 is the logarithmic index of 10, which has two digits; 2 is the logarithmic index of 100, which has 3 digits; 3 of 1000; 4 of 10,000, etc.

2d. That the logarithm of any number intervening between 1 and 10, must be a fraction less than unity; for the logarithm of 1 is 0, and of 10 it is 1; therefore the logarithm of any number between 1 and 10 must be less than 1. The logarithm that corresponds to any number between 10 and 100, must be greater than 1 and less than 2, etc.

3d. That the product of any two numbers in the series of geometrical progression, answers to the sum of the two numbers in the arithmetical order, which correspond to them. Thus; 100,000,000 in the geometrical, answers to 8 in the arithmetical order, and 100,000,000 is the product of $1000 \times 100{,}000$, which two numbers correspond with 3 and 5 in the arithmetical series; and in this series $3 + 5, = 8 =$ 100,000,000 in the geometrical series. Now 3 is the logarithm of 1000, and 5 of 100,000. Hence, therefore, if the logarithms of any quantities, whose product is required, be added together, this sum will be the logarithm of the required product.

4th. That the difference as 4, between any two numbers (6—2) in the series of the arithmetical order of progression, is the logarithm of the quotient (10,000) which arises from dividing by each other, the two numbers ($1{,}000{,}000 \div 100$) that correspond, in the geometrical order, to the two said arithmetical terms (2 and 6). And,

Digitized by Google

5th. That logarithms of numbers are a series of terms in the order of arithmetical progression, which series corresponds to another series of numbers in the order of geometrical progression.

§ *f*. The logarithm of 10 is not necessarily 1. Any other number as well as 1 may be assumed as the logarithm of 10. But if any other number were taken as the logarithm of 10, it would establish another base for calculating a table of logarithms, and this change would effect the logarithm of every other number in the same ratio. From this it appears that the value of a logarithm is entirely conventional. But in order to simplify, and facilitate their application to practice, mathematicians have assumed, in the order of geometrical progression, a series of numbers in the ratio of 1, 10, 100, 1000, 10,000, etc.; and as logarithms to these, they have assigned, in arithmetical progression, a series of numbers in the order of 0, 1, 2, 3, 4, etc., having 1 for the common difference. The latter numbers, taken in the order in which they stand, are called the logarithmic *indices*, or *characteristics*, of the former, taken in the same order. Whence (§ *e*. 1st) the logarithmic index of every whole number, is made always to express *one less* than the number of digits contained in the whole number. Thus, the characteristic of 100 is 2, as the number of digits or figures in 100, is 3. The number of digits in 1000 is 4, and the logarithmic characteristic of 1000, is 3.

§ *g*. The logarithmic signs and tangents, co-sines and co-tangents, etc. of degrees, minutes, and seconds, are also of conventional value. They are expressed in parts of the radius of a circle; the value of which radius is assumed to be equal to 10, etc., with as many cyphers affixed as the compiler intends the *mantissa* shall consist of digits.

§ *h*. The *mantissa* is the decimal part of the logarithm; or the part which is not the index. The logarithm of 250 is 2 .397940; 2 is the index, and .397940 is the mantissa.

The characteristic of a logarithm depends upon the number of digits which are contained in its *geometrical** number; being one less than the number of digits, it is known by counting the figures of the geometrical number, and writing down one less than their number for the index.

§ *i*. The mantissæ have been previously calculated and arranged in a tabular form, and in such a manner that the mantissa for any geometric number, (however great or small,) may be determined with readiness.

§ *j*. The first column of the tables (I.) is marked N. (Numbers.) It contains the geometrical numbers, from 1 to 999. The mantissa of each term in this series, is in a line with its geometrical number, and in the next column which is marked 0. The nine other columns, headed with the cardinal numbers 1, 2, 3, etc., to 9, also contain mantissæ; but these are of geometrical numbers that have *four* digits; the last figure of which, being found at the head of one of these columns, and the three first in the first column (N), show at their angle of meeting, the proper mantissa. Thus, the logarithm of 3681 is 3.565966; 368

* The natural numbers, which correspond to, or are represented by, a logarithm, are here called *geometrical* numbers, from their being terms in the geometrical series of progression. Thus 419, of which 2.622214 is the logarithm, is the *geometrical* number of log. 2.622214.

Digitized by Google

being found in the first column, N., the mantissa for 3681 is found in a line with 368, and in the column, at the top and bottom of which, stands 1.

TAKING OUT LOGARITHMS OF NUMBERS.

§ 84. To take from the table (I.) the mantissa for any geometrical number less than 1000.

§ *a.* Find the given number in the first column (N.); its mantissa is opposite to it in the next column (0).

§ *b.* The mantissa for 9 is .954243; for 14 it is .146128; and for 964 it is .984077.

§ *c.* These mantissæ, with the proper characteristics prefixed, constitute the logarithms of those numbers; thus, logarithm of 9 = 0.954243; of 14 = 1.146128; and of 964 = 2.984077.

§ 85. To take from the tables, the mantissa for any geometrical number that is greater than 1000, but less than 10,000.

§ *a.* Find, in the first column (N.) of the tables, the first three figures of the proposed number; in a line with them, and in the column over which the fourth figure stands, is the proper mantissa.

§ *b.* The mantissa (.973590) for 9410 is found in the column marked 0, and opposite to 941 in the first column; and the mantissa (.954918) for 9014, is found in the column marked 4, and opposite to 901 in the first column (N).

§ *c.* The geometrical numbers in this case have four digits; 3, then, is the characteristic of their logarithms; which are, 3.973590 = 9410; and 3.954918 = 9014.

§ 86. To take from the tables the mantissa of any geometrical number that has more than *four digits*, or that is greater than 10,000; say of 43568.

§ *a.* Take out the mantissa for the first four digits (§ 85. § *b.*), and subtract it from the mantissa next in order. Then say,—If unity (1, prefixed to as many cyphers as there are digits remaining of the proposed geometrical number,) give this mantissal difference, what mantissal difference will the remaining digits of the geometrical number, give? This last mantissal difference being added to the mantissa for the first four digits, produces the required mantissa.

§ *b.* The mantissa for the first four digits (4356) of 43568 is .639088; the mantissal difference between this and the next (.639188) in order, is .000100; one digit (8) of the proposed geometrical number remains; and unity (1) (§ *a.*) must be prefixed to one cypher (0), which makes (10); then the order and terms of the proportion are, 10 : .000100 : : 8 : .000080. This last term, *plus* the former mantissa, (or .639088 + .000080) = .639168, the mantissa required.

§ *c.* The geometrical number (43568) in this example has *five* digits; then (4) being prefixed as an index to the mantissa (.639168) makes the logarithm of 43568 = 4.639168.

§ *d.* The mantissa for the first four digits (7419) of 741946 is .870345; the difference between the mantissa of 7419, and of 7420, is .000059. And the order and terms of the proportion are, 100 : .000059

Digitized by Google

: : 46 : .000027. This last term being added, and the characteristic (5) being prefixed to the mantissa (.870345), makes the logarithm of 741946 = 5.870372.

§ *e*. The mantissa for the first four digits (5941) of 594106734 is .773860; the mantissal difference = .000073; the remaining digits (06734) are *five* in number. Prefixing 1 to *five* cyphers, the proportion is .100000 : .000073 : : 06734 : .000004. Prefixing the characteristic (8) to .773860 + .000004, makes the logarithm of 594106734 = 8.773864.

§ *f*. The mantissa for 124, and the mantissa for 1240000000 are the same (.093422). But the logarithm of 124 = 2.093422; and the logarithm of 1240000000 = 9.093422. Hence,

§ *g*. The effect of final cyphers in a geometrical number, on its logarithm, is confined to the characteristic of the logarithm, for the logs. (§ *f*.) of 124 and 1240000000 have the same mantissa.

LOGARITHMS OF MIXED NUMBERS.

§ 87. To find the logarithm of a geometrical number that is mixed with a decimal fraction.

§ *a*. The mantissa is found as it would be, were the proposed number integral; but the characteristic of the logarithm must express one less than the number of digits in the *integral* part of the number proposed. Thus:

Mixed Geometrical Nos.	Their Logarithms.
9414.5 - - -	= 3.973797
941.45 - - -	= 2.973797
94.145 - - -	= 1.973797
9.4145 - - -	= 0.973797

§ 88. As the logarithm of unity, or (1), is 0, it follows that the logarithm of any quantity less than unity, or the logarithm of a fraction, must be less than 0; that is, it is a *negative quantity*. Thus,—

Logarithm of	1 =	0	.000000
Logarithm of	0.1 =	— 1 +	.000000
Logarithm of	80 =	1	.903090
Logarithm of	0.08 =	— 2 +	.903090

§ *a*. But the use of negative and positive quantities (such as the logarithms of integers and of fractions, as just quoted above), in the same operation, has a tendency sometimes to perplex the calculator. It is better, therefore, that all quantities in the same sum should be affected with like signs. This may be effected with the logarithms of fractions by means of a little artifice, by which negative quantities are made to change their signs, or become as positive quantities.

§ *b*. This artifice consists in borrowing and applying 10, or 20, or 100, etc., to the logarithmic index of the fraction, and restoring the borrowed quantity again during the process of calculation. Thus, in the summing up of the logarithms of 80, and of 0.08: instead of adding the mantissæ and subtracting the characteristics of the two logarithms (1.903090 — 2 + .903090 = 0.806180), the operation may be performed entirely by addition, if the arithmetical complement

Digitized by Google

of — 2, which is 8, be used as the index; thus, 1.903090 + 8 + .903090 = 10.806180; rejecting the 10, which was borrowed in the logarithmic index of 0.08, there remains 0.806180.

THE ARITHMETICAL COMPLEMENT.

§ *c.* Any quantity with the sign — prefixed, may be commuted into a positive quantity by substituting for that quantity its *arithmetical* complement. In this way subtraction may be performed by addition, as we have seen (§ *b.*) in the case of the negative index — 2.

§ *d.* The *arithmetical complement* of a number, is the difference between that number, and the first number that ends with a cypher, and is one scale higher in the decimal order of notation. The arithmetical complement of 6, is 4, (10 — 6 = 4); of 77, is 23, (100 — 77 = 23); of 115, is 885, (1000 — 115 = 885), etc.

§ *e.* If it be required to subtract 6 from 9, the result is the same, whether we say 9 — 6 = 3, or take the arithmetical complement (4) of 6, add it to 9, (4 + 9 = 13), and reject the borrowed 10 from their sum (13 — 10 = 3).

§ 89. To find the arithmetical complement of a logarithm.

§ *a.* Prefix *one* or *unity* to as many cyphers as there are digits in the proposed logarithm; then from this number subtract the proposed logarithm, and the remainder will be the required arithmetical complement.

§ *b.* Thus, the arithmetical complement of 1.903090 is 8.096910; for 10000000.

1.903090

8.096910

§ *c.* The same result may be obtained by beginning at the left, and subtracting from 9, every figure except the last significant one, which must be subtracted from 10.

Thus— 9.9999(10)0
1.9030 9 0

8.0969 1 0

§ *d.* If the index be greater than 9, it must be subtracted from 19.

LOGARITHMS OF FRACTIONS.

§ 90. To find the logarithm of a decimal fraction.

§ *a.* The mantissa for the proposed fraction is taken from the table, as for an integral geometrical number of the same significant figures which the fraction has.

§ *b.* The logarithm for the same figures expressed both integrally and fractionally, differs only in the characteristic; the mantissa is the same in both cases. Therefore we have only to teach how to determine a *positive* characteristic, or the logarithm of a decimal fraction.

§ *c.* The characteristic is determined by means of the number of cyphers which precede the first significant figure of the decimal; for the number of these subtracted from 9, gives the required characteristic.

Digitized by Google

Thus, logarithm of the decimal .301 = 9.478567
Logarithm of the decimal .0301 = 8.478567
Logarithm of the decimal .000301 = 6.478567

§ 91. To find the logarithm of a vulgar fraction that is less than unity.

§ *a.* Take from the tables the mantissa for the numerator, and for the denominator, separately, and as if each were a whole number expressed by the same figures. Then, from the logarithm of the numerator, *plus* 10 to the index, subtracting the logarithm of the denominator, leaves the logarithm of the proposed fraction. Thus,

§ *b.* To find the logarithm of $\frac{25}{100}$.

Logarithm of 25 = 1.397940
Logarithm of 100 = 2.000000

Logarithm of $\frac{25}{100}$ = 9.397940

To find the logarithm of $\frac{3}{8}$.

Logarithm of 3 = 0.477121
Logarithm of 8 = 0.903090

Logarithm of $\frac{3}{8}$ = 9.574031

§ 92. To find the logarithm of a mixed number.

§ *a.* If the number proposed (9.05) consist of a whole and a decimal fraction, take from the tables the mantissa for the mixed number as if it were a whole, and then prefix the index, *which expresses one less than the number of digits in the integral part* of the mixed number proposed. Thus, the index of the logarithm for 9.05 is 0, and for 90.5 it is 1; the mantissa (.956649) is the same for each number; because it is taken out for the figures (905) as though they stood for a whole number.

Then, the logarithm of 9.05 = 0.956649
The logarithm of 90.5 = 1.956649

§ *b.* But if the proposed mixed number consist partly of a vulgar fraction, let it be reduced to an improper fraction: then find the logarithm of the numerator, and of the denominator, as if they were separately whole numbers; and the logarithm of the numerator, *minus* logarithm of the denominator, is the required logarithm.

Thus, logarithm $12\frac{2}{3}$ = 1.102663; for $12\frac{2}{3}$ reduced to an improper fraction is $\frac{38}{3}$; and

Logarithm 38 = 1.579784
Logarithm 3 = 0.477121

1.102663 = $12\frac{2}{3}$

§ *c.* The index to the logarithm of an improper fraction, is always a *proper* index; for the numerator being greater than the denominator of such a fraction, the logarithm of the latter can be subtracted from that of the former, without borrowing 10 in the index.

TAKING OUT THE NATURAL NUMBERS.

§ 93. To find the geometrical number which corresponds to a logarithm.

Digitized by Google

§ *a.* The number of digits in a geometrical number for a logarithm, is known by the characteristic of a logarithm; for 1 added to the *characteristic* tells the number of digits.

§ *b.* Find, in the table, the mantissa of the proposed logarithm. The figures in the first column (N,) being prefixed to the figure that stands at the top of the column in which the mantissa is found, compose the geometrical number that is required.

§ *c.* The geometrical number of log. 3.759214 = 5744.
The geometrical number of log. 2.759214 = 574.4.
The geometrical number of log. 1.759214 = 57.44.
The geometrical number of log. 0.759214 = 5.744.

This mantissa is found in the column (4) of the table, and opposite to 574 in the first column (N.).

§ *d.* Had the index of the logarithm been greater than 3, the number of digits for the geometrical number required would have been made up by affixing cyphers to the numbers (574 and 4) found above, and opposite to, the mantissa. Thus, the geometrical number for 4.976854 is known (§ *a.*) to consist of *five* digits, because of the index (4). The mantissa (.976854) is found opposite to 948 (in the column N.), and under 1; making up with cyphers, the proper number of digits.

The geometrical number for 4.976854 = 94810.
The geometrical number for 5.976854 = 948100.
The geometrical number for 6.976854 = 9481000.

§ *e.* If the proposed mantissa cannot be found in the tables, take that mantissa in the tables, which, being less, comes nearest to it, and affixing any number of cyphers to the difference between these two mantissæ, divide it by the difference between said tabular mantissa and the one next in order after it; the quotient, being affixed to thenumbers opposite to, and at the head of the column of, said least mantissa, comprises the figures of the required geometrical number. The digits for the integral part of the geometrical number are determined by the index of the proposed logarithm (§ *a.*), and the figures which are to the right of these digits, constitute the fractional part of the geometrical number. Thus,

§ *f.* Geometrical number for 4.979744 = 95443.
Geometrical number for 2.979744 = 954.43.
Geometrical number for 0.979744 = 9.5443.

The proposed mantissa (979744) cannot be found in the tables. The difference between the next less (.279730) and the next greater (979776) found in the tables, is 46; and the difference (14) between the less of these two and the proper mantissa being prefixed to any number of cyphers, (14000----), and divided by the tabular difference (46), gives 3 + to be affixed to the four figures 9544, from which the required digits for the integral part of the geometrical number, are to be separated according to the index of the logarithm proposed.

§ *g.* If the index of the logarithm proposed be an *improper* characteristic, the geometrical number of the logarithm is a decimal fraction. And the difference between this characteristic and 9, tells how many

Digitized by Google

cyphers must intervene between the decimal point (.) and the first significant figure of the fraction. Thus, (the indices being *improper*),

The geometrical number for $7.911424 = 0.008155$.
The geometrical number for $9.897627 = 0.79$.
The geometrical number for $5.698970 = 0.00005$.

§ 94. To perform multiplication by logarithms.

§ *a*. Add the logarithms of the factors together; the sum of these is the logarithm of the product. Thus,

§ *b*. To multiply 3 by 4; 20 by 2.5; and .25 by .30.

Logarithm $3 = 0.477121$ Logarithm $20 = 1.301030$
" $4 = 0.602060$ " $2.5 = 0.397940$

$1.079181 = 12$ $1.698970 = 50$

Logarithm $0.25 = 9.397940$
" $0.30 = 9.477121$

$8.875061 = 0.075$

§ 95. To perform division by logarithms.

§ *a*. Subtract the logarithm of the divisor from the logarithm of the dividend, the remainder will be the logarithm of the quotient.

§ *b*. To divide 36 by 3; 8941 by 19; 50 by .05; and 82.7 by 70.91.

Log. $36 = 1.556302$ Log. $8941 = 3.951386$
" $3 = 0.477121$ " $19 = 1.278754$

$1.079181 = 12.$ $2.672632 = 470.57 +$

Log. $50 = 1.698970$ Log. $82.7 = 1.917506$
" $.05 = 8.698970$ " $70.91 = 1.850708$

$3.000000 = 1000$ $0.066798 = 1.16 +$

§ 96. To perform involution by logarithms.

§ *a*. Multiply the logarithm of the proposed geometrical number by the index (§ X.) of the power to be involved; this product will be the logarithm of the required power.

§ *b*. Raise 8^2, 17^3, 112^4, 516^9.

Log. $8 = 0.903090$ Log. $17 = 1.230449$
$\times 2$ $\times 3$

$1.806180 = 64$ $3.691347 = 4913$

Log. $112 = 2.049218$
$\times 4$

$8.196872 = 157351936$

Digitized by Google

Log. 516 = 2.712650
9

24.413850 = 25932674841320831763087 36

§ *c.* If the geometrical number that is proposed to be raised, be a decimal fraction, the difference between the characteristic of the logarithm of the power, and the product of 10 by the index of the power involved, expresses *one* more than the number of cyphers that must precede the first significant figure of the required power.

§ *d.* To raise $.17^3$, $.05^1$, $.064^5$

Log. 0.17 = 9.230449
3

27.691347 = 0.00491 +

Log. 0.05 = 8.698970
2

17.397940 = 0.0025

Log. 0.064 = 8.806180
5

44.030900 = 0.000001073 +

§ 97. Evolution is the converse of involution.

§ *a.* To perform evolution by logarithms.

§ *b.* The quotient, obtained by dividing the logarithm of the power proposed, by the exponent (§ XII.) of the root to be extracted, is the logarithm of the root required.

§ *c.* To evolve the square root of 196, the $\sqrt[3]{}$ of 81, and the $\sqrt[7]{}$ of 128.

Log. 196 = 2.292256 ÷ 2 = 1.146128 = 14.
Log. 81 = 1.908485 ÷ 3 = 0.636161 + = 4.326 +.
Log. 128 = 2.107210 ÷ 7 = 0.301030 = 2.

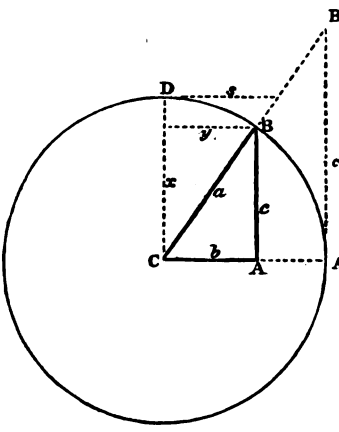
§ *d.* If the geometrical number whose root is to be evolved, be a decimal fraction; in order to obtain the logarithm of the root required, the exponent, less *one*, of the root to be extracted, must be prefixed to the characteristic of the logarithm of the number proposed; and then the quotient, that arises from dividing this quantity by the exponent of the root to be evolved, will be the logarithm of the power required. Thus, to find the cube root of .27. The logarithmic index of 0.27 is 9; now, to 9, prefixing *one* less (2) than the exponent (3) of the root to be evolved, makes the logarithm of 0.27 = 29.431364 ÷ 3 = 9.810454 + = 0.646 +. To find the square root of 0.00776, the logarithmic index of which is (7); prefixing to 7 *one* less (1) than the exponent (2), makes the logarithm of 0.00776 = 17.889862 ÷ 2 = 8.944931 = 0.088 +.

§ 98. Radius is the base of the system of logarithms contained in tables II., pp. 23. 75. In these tables, all radii, like the circumferences of all circles (§ 49. § *c.*), are considered equal; *i. e.*, each rad. as bearing the same proportion to the entire circumference of its circle. Rad. therefore is assumed as 1, or the linear unit in the logarithmic arrangement of the trigonometric functions (§ 57. § *c.*); because the *ratio* between the circumference of every circle and its radius (§ 76. § *e.*) is a constant

Digitized by Google

ratio—radius being always equal, as just intimated, to an arc of its circle of 57° 17′ 45″ (nearly).

§ *a*. The logarithms of the trigonometric functions, as of sine, tangent, secant, cos., cot., and co-sec., contained in these tables (pp. 23. 75), therefore, are the *exponents* (§ XII. § *a*.) of the ratio between rad. unity, and the log. sine, tangent, etc. of the various arcs or angles therein named. Thus, 9.534052, (the log. sine, p. 51, of 20°,) is the exponent of the ratio between rad. unity and the sine of an arc or angle of 20°. So with tang., cotang., cos. and sec., etc.: for, being sides of similar triangles (§ 23. § *c*.), these functions are therefore (§ 73. and § 75.) proportional to each other, and (§ 76.) to the constant ratio, called rad., to which they are all related, *e. g.*



§ *b*. Let C A B be a triangle right angled at A. From C as a centre, and with *a* as rad., describe the circle D B A′. Draw *c*′ (§ 56.) as tangent of the central angle C, and produce *a* to B′ as the secant (§ 57.) of the same angle. Also draw *y* and *s*: *c* is the sine, (§ 54.), *y* or *b*, the cosine (§ 57. § *a*.), and *s* the cotangent, of C.

§ *c*. C A B and C A′ B′ (§ 23. § *b*.) are similar triangles. By construction, and by § 30. § *d*. and § 54. *c* and *x* are parallel; so also are *y* and *b*; *y c b x* (§ 19.) is therefore a parallelogram, and its opposite sides, *y* and *b*, *c* and *x*, are equal. In the given triangle, B (§ 32. § *d*.) is the complement of C; B (§ 30.) is equal to B C *x*, and *y* (§ 54.) is the sine of B C *x*, or the sine of the complement of C. Wherefore *y*, (§ 52. § *d*.) the cos. of C, is equal to *b*. Therefore *b* is also cos. C.

§ *d*. Bearing in mind these relations of the several parts, sine C (§ 75.) : rad. : : *c* : *a*—and (§ XLV.) sine $\frac{\text{C}}{\text{rad.}} = \frac{c}{a}$. But (§ 98.) rad. = 1. Therefore sine $\frac{\text{C}}{1} = \frac{c}{a}$, or $\frac{c}{a}$ is sine C; and so of $\frac{\text{cos. C}}{\text{rad.}} = \frac{b}{a}$.

§ *e*. So also in the triangle C A′ B′ (§ 75.) *c*′ : C A′ : : *c* : *b* : : But (§ 50. § *a*.) C A′ is equal to *a*. Therefore (§ 69. and § XLV.) $c' \div a = c \div b$. But *a* is rad. = 1, and *c*′ is tang. C. Wherefore $\frac{c'}{1} = \frac{c}{b}$ or $\frac{c}{b}$ equals tang. C.

§ *f*. Again, and for like reasons, C B′ ÷ C A′ = $a \div b$. C A′ is rad. = 1, as before, and C B′ the secant (§ 57.) of C. Wherefore $\frac{a}{b}$ equals sec. C.

§ *g*. Recapitulating the results of § *d*. § *e*. and § *f*. for more convenient reference, we have—

Digitized by Google

1. (§ *d.*) $\frac{c}{a}$ = sine C.

2. (§ *e.*) $\frac{c}{b}$ = tang. C.

3. (§ *f.*) $\frac{a}{b}$ = sec. C.

§ *h.* Repeating, with regard to the angle *a* C *x*, in the triangle B C *x*, the demonstrations used at § *d.* § *e.* and § *f.* with regard to C in the given triangle, we have—

4. (§ *d.*) $\frac{y}{a}$ = sine *x* C *a*.

5. (§ *e.*) $\frac{y}{x}$ = tang. *x* C *a*.

6. (§ *f.*) $\frac{a}{x}$ = sec. *x* C *a*.

But (§ *c.*) *x* C *a* is the complement of C; *y* equal to *b*, and *x* to *c*. § *i.* Wherefore (§ 24. § *b.*) and (§ *h.*),

4. Cos. C = $\frac{b}{a}$, which is the reciprocal of $\frac{a}{b}$ = sec. C (§ *g.* 3.)

Therefore log. cos. C is ar. co. of log. sec. C.

5. Cot. C = $\frac{b}{c}$, which is the reciprocal of $\frac{c}{b}$ = tang. C (§ *g.* 2.)

Therefore log. cot. C = ar. co. log. tang. C.

6. Co-sec. C = $\frac{a}{c}$, which is the reciprocal of $\frac{c}{a}$ = sine C (§ *g.* 1.)

Therefore log. co-sec. C = ar. co. log. sin. C.

These ratios expressed in decimal fractions, are the Logs. given in Table II.

§ *j.* With this explanation, it appears that the trigonometric functions, viz: sines, tangs. and secants, with their complements, are properly numbers; which numbers (§ *a.*) are the exponents of the ratios of certain right lines, and by which the values of all arcs and angles may be computed.

The logs. or exponents of these ratios are given in Table II. for arcs and angles both in degrees and in time (an hour being considered as equal to 15°,* 1^m, = 15′, and 1^s = 15″; and, reciprocally, 1° = 4^m, 1′ = 4^s); they are carried out for every 15″ of space or 1^s of time, from 15″, or 1^s to 1°, or 4^m; for every 30″ of space, or 2^s of time from 1° or 4^m to 6° or 24^m; and for every 1′ or 4^s, from 6° or 24^m, to 45° or 3^h; and for their complements. Thus, to find in the tables the Log. sin. of 2^h 40^m 33^s, or of its equivalent 40° 8′ 15″: the number in the "Diff" column for sine and co-sec., and opposite to 2^h 40^m 32^s, or 40° 8′, (the tabulated value nearest to the given arc or angle) is .000037. The Log. sine increases

* 15° × 24 = 360°. Wherefore the circumference of a circle, measured in time, is equal to 24 hours. The division of the circle into hours is an important one to the navigator. The Right Ascension of all heavenly bodies is usually expressed in time, and time is the great element of longitude—longitude being (§ 390.) only the difference of time between two places.

Digitized by Google

with the value of the angle; therefore as the given angle is greater than the tabulated angle, .000037 must be added for every 15″ of space, or 1ˢ of time, and so on in proportion, *e. g.*

Log. sine 2ʰ 40ᵐ 32ˢ, or 40° 8′			= 9.809269
add, for	1ˢ, or	15″	37
Log. sine 2ʰ 40ᵐ 33ˢ, or 40° 8′		15″	= 9.809306

§ *k.* In trigonometric calculations by logarithms, it often happens that a solution, though good in theory, is bad in practice, on account of certain functions used in the process of calculation. Thus the log. cos. or sec. of a very small angle, and the log. sine or co-sec. of a very large one, when used in the solution of a problem will always vitiate the result, and for reasons growing out of the relations between arcs or angles near 90° and their sines and co-secants, or between very small angles and their secants and cosines. Thus, suppose the formula used in the logarithmic solution of a problem involve the sine of an angle near 90°. The table of log. sines, etc., (p. 23,) shows no difference in the log. sine of all the angles ranging from 89° 55′ to 90° 5′.

§ *l.* Therefore, when the formula for calculation embraces the sine of a very large angle, or the cos. of a small one, it becomes necessary, in such cases, to substitute for sine and cos., their equivalents under the denomination of tang. and cotang., etc. The equations (§ *i.*) indicate those equivalents. Referring again to those equations, and recollecting (§ *b.*) that *a* is rad., *c* the sine, and *b* the cos., C, we have the following:

§ *m.*

(2) (§ *g.* 2). $\frac{c}{b}$ = tang. C. By substitution, (§ 69.)

- sin. C ÷ cos. C = tang. C; and, (§ XLI.),
- sin. C ÷ tang. C = cos. C. Also, (§ XLI.),
- cos. C × tang. C = sin. C.

Wherefore,

- $\frac{\text{sin.}}{\text{cos.}}$ = tang. 1
- $\frac{\text{sin.}}{\text{tang.}}$ = cos. 2
- cos. × tang. = sin. 3

(§ *g.* 3.) $\frac{a}{b}$ = sec. C = By substitution, (§ 24. § *b.*)

- rad. ÷ cos. C = sec. C, and (§ XLI.),
- rad. ÷ sec. C = cos. C. Also, (§ XLI.),
- cos. C × sec. = rad.

Wherefore,

- $\frac{\text{rad.}}{\text{cos.}}$ = sec. 4
- $\frac{\text{rad.}}{\text{sec.}}$ = cos. = $\frac{\text{sin.}}{\text{tang.}}$ (2) 5
- cos. × sec. = rad. 6

(§ *h.* 5.) $\frac{b}{c}$ = cot. C = By substitution,

- cos. C ÷ sin. C = cot. C
- cos. C ÷ cot. C = sin. C
- sin. C × cot. C = cos. C

Wherefore,

- $\frac{\text{sin.}}{\text{cos.}}$ = cot. 7
- $\frac{\text{cos.}}{\text{cot.}}$ = sin. = cos. × tang. (3) 8
- sin. × cot. = cos. = $\frac{\text{rad.}}{\text{sec.}} = \frac{\text{sin.}}{\text{tang.}}$ (5) 9

Digitized by Google

$$\frac{a}{c} = \text{co-sec. C} = \left\{\begin{array}{l}\text{By substitution,}\\ \left[\begin{array}{l}\text{rad.} \div \text{sin. C} = \text{co-sec. C.}\\ \text{rad.} \div \text{co-sec. C} = \text{sin. C.}\\ \text{sin. C} \times \text{co-sec. C} = \text{rad.}\end{array}\right.\end{array}\right\} \text{Wherefore,} \left\{\begin{array}{ll}\frac{\text{rad.}}{\text{sin.}} = \text{co-sec.} & 10\\ \frac{\text{rad.}}{\text{co-sec.}} = \text{sin.} = \frac{\text{cos.}}{\text{cot.}} = \text{cos.} \times \text{tang.} & (8)\ 11\\ \text{sin. . co-sec.} = \text{rad.} = \text{cos.} \times \text{sec.} & (6)\ 12\end{array}\right.$$

Recollecting, moreover, (§ 43.) that $c^2 + b^2 = a^2$; and that a (§ 98.) is rad. *unity*, or 1, it appears (§ *b.* and § 24. § *b.*) that $c^2 + b^2$, or their equivalents (§ *b.*) sin.^{2}C + cos.^{2}C = rad.^{2}, or 1; and that therefore sin.^{2} + cos.^{2} = rad.^{2}

By multiplying (2 § *h.* and 5 § *h.*), we have (§ XLIII.) $\frac{c}{b} \times \frac{b}{c} = c^2 + b^2$. And (§ 43.) $c^2 + b^2 = a^2$, wherefore $\frac{c}{b} \times \frac{b}{c} = a^2$. But (13) a^2 = rad. unity, $\frac{c}{b}$ = tang. C. (§ *g.* 2 and § *h.* 5) and $\frac{b}{c}$ = cot. C. Therefore (§ 24. § *b.*) tang. C × cotang. C = rad., or 1; whence, tang. × cotang. = rad., or (§ XLI.) $\frac{\text{rad.}}{\text{tang.}} = \text{Cot. or } \frac{\text{rad.}}{\text{cot.}} = \text{tang.}$ 14

§ *n.* Besides showing that cos. ÷ cot., or cos. × tang. (§ *m.* 11) may be substituted in calculation for sin. : and that sin. × cot., or sin. ÷ tang. (§ *m.* 9) may be substituted for the cos. (§ *k.*) of a small angle, the foregoing equations exhibit many other valuable principles in logarithmic computations, *e. g.*—

1. The cos. and sec. (§ *m.* 6) are reciprocals.
2. Sin. and co-sec. (§ *m.* 12) are reciprocals.
3. Tang. and cotang. (§ *m.* 14.) are reciprocals.

Multiplication being performed by addition, and division by subtraction (§ 80) in logarithms, it follows from 1, or from (§ *m.* 6) that the Log. cos. and sec. of angle, being added together, give rad., and (§ *m.* 4 and 5) either being subtracted from rad. gives the other. So with the sin. and co-sec., (§ *m.* 10, 11 and 12) and (§ *m.* 14) with tang. and cotang. Thus, by the tables, p. 51—

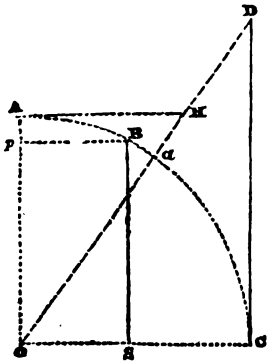
§ *o.*	Rad. = 10.000000	Rad. = 10.000000	Rad. = 10.000000
20°	Log. sine = 9.534052	Cos. = 9.972986	tang. = 9.561066
	0.465948 = co-sec. 20°	0.027014 = sec. 20°	0.438934 = cot. 20°

§ *p.* By the equations of § *m.* it also appears that if any one of the trigonometric functions, viz., sine or cos., sec. or co-sec., tang. or cotang., be given, all the others may be determined. The doing of which will afford a useful exercise to the learner.

§ *q.* Wherefore it appears that the Log. value of Rad., like the Log. value of 1, or 10, in the geometrical order, is conventional.

§ *r.* Hence it appears also that the *reciprocals* of sine, cos. and tang., are co-sec., sec. and cot.; and that sine and co-sec., cos. and sec., tang. and cot., are mutually the arithmetical complements of each other, that is, co-sec. of an angle is what its sine wants of 10.000000.

Digitized by Google



§ 99. If an arc of 90°, or if a right angle, be divided into any two parts, the sine or the tangent of either part, is the co-sine or co-tangent of the other. Thus, in the quadrant A B C; A B = 30°, B C = 60°, A *a* = 35°, and *a* C = 55°; P B is the sine of A B = 30°, and co-sine of B C = 60°; B S is the sine of 60° (B C), and co-sine of 30° (A B); therefore the co-sine of A B is B S, which is sine of B C, and the co-sine of B C is B *p*, which is sine of A B. In the same manner A H and C D are reciprocally the tangents and co-tangents of A *a* and *a* C. Wherefore the tables, by being calculated as far as 45°, answer for the whole circle, or for two right angles.

§ 100. The logarithmic value of the sec. of an arc, or an angle, is the arithmetical complement of the logarithmic co-sine of the same arc or angle.

§ *a*. The logarithmic co-sec. (§ 98. § *r*.) is the arithmetical co. of the logarithmic sine, and the logarithmic co-tangent is the arithmetical co. of the logarithmic tangent, and *vice versâ* (Vide § 109. § *h*.).

§ *b*. Wherefore in logarithmic tables of the trigonometric functions, it is only essential that the logarithms of the sine, co-sine, and tangent, or of the sec., co-sec., and co-tangent, should be given, for the first three are the arithmetical co. of the latter, and *vice versâ*; but to facilitate beginners in their calculations, the logarithmic sine, co-sec., co-sine, secant, tangent, and co-tangent, for every degree (°) and minute (′), are given in the tables (II.), as well as for every hour (H), minute (*m*), and 4ˢ (*s*), of the day.

§ 101. In trigonometrical calculations, when any logarithm is to be subtracted, the proper result may be obtained by adding the arithmetical co. of such logarithm.

§ *a*. This method of changing subtraction into addition is found very convenient in practice. After a little exercise in it, the arithmetical co. of a logarithm may be read from the logarithm, as readily as the logarithm itself is read from the tables.

§ *b*. Wherefore in the solution of trigonometrical problems, subtraction need never be performed, for (§ 101.) instead of subtracting a logarithm, the same result is obtained by substituting, for this logarithm, its arithmetical co., and adding this arithmetical co. in the calculation; therefore (§ 100. § *a*. and § 98. § *r*.),

When
- A logarithmic sine of an arc or an angle is to be subtracted, add its co-sec., and *vice versâ*.
- A logarithmic co-sine of an arc or an angle is to be subtracted, add its sec., and *vice versâ*.
- A logarithmic tangent of an arc or an angle is to be subtracted, add its co-tangent, and *vice versâ*.

Digitized by Google

§ 102. To find in the tables (II.), the logarithmic value of the sine of an arc or an angle.

§ *a*. If the proposed arc or angle be an *extreme* one, the number of *degrees* contained in it, is at the top of the page. But if the one proposed be a *mean* arc or angle, the *degrees* contained in it, are to be found at the *bottom* of the page.

§ *b*. An *extreme* arc or angle is one that contains *less* than 45°, or *more* than 135°. A *mean* arc or angle contains *more* than 45° but *less* than 135°.

§ *c*. If the proposed arc contain *less* than 45° or 3 H, or having more than 90° or 6 H, contain *less* than 135° or 9 H, the odd minutes of it are to be found in the proper minute column at the left of the page. But if it be *greater* than 135° or 9 H, or being greater than 45° or 3 H, contain less than 90° or 6 H, the odd minutes of it are contained in the minute column, that is at the right hand side of the page.

§ *d*. The columns marked at the bottom, Cos., Sec., Sin., Co-sec., Co-tang., and Tang., contain the logarithmic co-sine, secant, sine, co-sec., co-tang., and tang., of the degrees, etc., that are at the *bottom* of the page. And those marked Sin., Co-sec., Cos., Sec., Tang., and Co-tang., at the top, contain the logarithmic sine, co-sec., co-sine, secant, tangent, and co-tangent of the degrees, etc., at the *top* of the page.

§ *e*. To take out of the tables the logarithmic sine of an extreme arc, that is *less* than 45°, say of 34° 40′. The degrees (34°) of the arc proposed being found at the top of the page, and the minutes (40′) in the minute (′) column at the left of the page, the logarithm (9.754960) which, in the column of Sin. stands opposite to the minutes (40′), is the required logarithm. In the same way the logarithmic co-sine, or tangent, etc., is found in its proper column, and opposite to the given minutes.

Co-sine 21° 14′ logarithm = 9.969469.

Tangent 19° 56′ logarithm = 9.559491.

§ *f*. If the arc (179° 7′) proposed be extreme, and greater than 135°, the odd minutes (7′) must be found in the last minute (′) column on the page; the required logarithm (8.187985) is then found opposite, and in the column marked (Sin.) at the top.

§ *g*. The odd minutes of a mean arc, say 61° 12′, that is *less* than 90°, are found in the last minute (′) column; and those of one, say 114° 59′, that is *greater* than 90°, are found in the first minute (′) column of the page; and the character (Sin., Cos., Co-tang.) of the column is taken from the bottom of the page.

Sine 61° 12′ = 9.942656.

Co-tangent 114° 59′ = 9.668343.

Tangent 114° 59′ = 10.331657.

§ *h*. The trigonometric functions of hours, minutes and seconds, are taken from the tables in the same way.

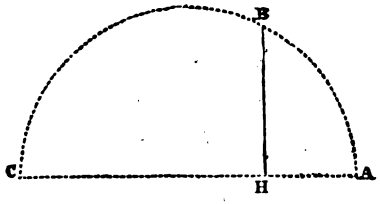
§ 103. To find the degs. etc. for a log. sine.

§ *a*. The minutes, in the minute (′) column, which are found opposite to the proposed logarithm, and the degrees, which stand where the column in which the proposed logarithm is found, is marked Sin., are

Digitized by Google

the degrees and minutes required. The same directions answer for taking out the tangent, secant, co-sine, etc. of a logarithm. Thus,

Logarithm 9.627300 sine = 25° 5′ or 154° 55′.
" 9.956566 cos. = 25° 12′ or 154° 48′.
" 9.831709 tang. = 34° 10′ or 145° 50′.
" 9.745494 cos. = 56° 11′ or 123° 49′.
" 10.377793 tang. = 67° 16′ or 112° 44′.



§ *b.* An arc (A B) and its supplement (B C) have the same sine (B H); therefore the same logarithm answers either to the sine of A B or B C. But, for the most part, in calculations, there is some circumstance connected with the problem, which determines whether an arc or its supplement be required. If not, the case or the solution is called *doubtful.* The same remarks apply to co-sines, secants, tangents, etc.

PLANE TRIGONOMETRY.

§ 104. Plane trigonometry is that branch of mathematics by which, with certain data, the unknown parts of triangles are determined.

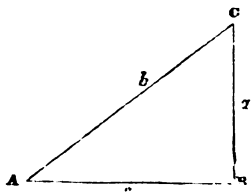
§ *a*. Plane trigonometry is divided into right and oblique, angled trigonometry. The solution of right angled triangles pertains to the former; and that of oblique angled triangles to the latter. The methods of solving problems in either, in most cases are similar.

§ *b*. Every plane triangle consists of three sides and three angles; which, in a general term, are called *the six parts* of a triangle.

§ *c*. If the value of any three of these six parts (the *three* angles excepted), be known, the value of every one of the remaining parts is determinable by trigonometrical operations.

§ *d*. When the angles constitute the only data, the sides cannot be determined (except in *species*); because there may be any number of triangles which are equiangular to each other, and their homologous sides may all be unequal, as the sides of the two triangles under § 73. are.

§ 105. In trigonometrical calculations it frequently becomes necessary to change one function for another, or for parts of another. It is proper, therefore,—the importance of which will be seen hereafter—to investigate at least a few such formulæ.



§ *a*. Let A B C be right angled at B. Now (§ 43.) $c^2 + a^2 = b^2$, or $c \times c + a \times a = b \times b$.

§ *b*. By § 54. *a* is the sine and *c* the co-sine of A. A + C (§ 32. § *c*.) = 90; wherefore the sine of (A + C) (§ 62.) is equal to Rad. or *b*.

§ *d*. Hence we have sine C × cos. A (the same (§ *a*.) as $c \times c$) + sine A × cos. C (the same (§ *a*.) as $a \times a$) $= b^2$ or R^2. But (§ 98.) R is 1; therefore $R^2 = 1$, and (§ *b*.) sine (A + C) = R. Also (§ 43.) $\cos.^2 A = R^2 - \sin.^2 A$.

§ *e*. Wherefore sine (A + C) = sine A cos. C + sine C cos. A; or the sine of the sum of any two angles of a triangle is equal to the rectangle under the sine of the first and co-sine of the second, plus the rectangle under the sine of the second and co-sine of the first.

§ *f*. In the same manner it may be proved that sine (A — C) = sine A cos. C — sine C cos. A. Also

§ *g*. Cos. (A + C) = cos. A cos. C — sine A sine C.

§ *h*. Cos. (A — C) cos. A cos. C + sine A sine C. And so of tangents, etc.

Digitized by Google

§ *i*. If we suppose A and C to be equals in equations § *e*. and § *g*., we shall have by the former, sin. 2 A = 2 sin. A cos. A, and by the latter, cos. 2 A = cos. ^{2}A — sine ^{2}A = 2 cos. ^{2}A — R^2.

These formulæ are used for determining the sine and cosine of the double arc, when the sine and cos. of the arc itself are known.

§ 106. A variety of other useful formulæ may be derived from equations § *e*. § *f*. § *g*. and § *h*. (§ 105.), a few of which only we will investigate here to aid in subsequent demonstrations.

§ *a*. By adding the first two, we have sin. (A + C) + sin. (A — C) = 2 sin. A cos. C.

§ *d*. By subtracting them, we obtain sin. (A + C) — sin. (A — C) = 2 sin. C cos. A. Doing the same with the last two we have in like manner:

§ *e*. Cos. (A + C) + cos. (A — C) = 2 cos. A cos. C.

§ *f*. Cos. (A — C) — cos. (A + C) = 2 sin. A sin. C.

§ *g*. Now if we put *s* = A + C, and *d* = A — C, and recollect the equivalents (§ 77. § *g*.) for the half sum and half difference of any two quantities, we shall have:

Sin. *s* + sin. *d* = 2 sin. $\frac{1}{2}$ (*s* + *d*) cos. $\frac{1}{2}$ (*s* — *d*).

§ *h*. Sin. *s* — sin. *d* = 2 sin. $\frac{1}{2}$ (*s* — *d*) cos. $\frac{1}{2}$ (*s* + *d*).

§ *i*. Cos. *s* + cos. *d* = 2 cos. $\frac{1}{2}$ (*s* + *d*) cos. $\frac{1}{2}$ (*s* — *d*).

§ *j*. Cos. *s* — cos. *d* = 2 sin. $\frac{1}{2}$ (*s* + *d*) sin. $\frac{1}{2}$ (*s* — *d*).

Now recollecting (§ 98. § *m*.) $\frac{\text{sin.}}{\text{cos.}}$ = tang., we may derive from these four equations in connection with the formulæ under § *i*. (§ 105.), numerous other formulæ, each of which may express some useful theorem, *e. g*., dividing equation § *g*. by § *h*., we have:

§ *k*. $\frac{\text{Sine } s + \text{sine } d}{\text{Sine } s - \text{sine } d} = \frac{\text{sine } \frac{1}{2}(s+d)\cos.\frac{1}{2}(s-d)}{\cos.\frac{1}{2}(s+d)\text{ sine }\frac{1}{2}(s-d)} = \frac{\text{tang. }\frac{1}{2}(s+d)}{\text{tang. }\frac{1}{2}(s-d)}$ (§ 98. § *n*.)

§ *l*. Which is another expression for the theorem (§ 77,) that the sum of the sines of any two arcs or angles is to the difference of their sines, as the tangent of half their sum is to the tangent of half their difference.

§ *m*. Further: returning to equation § *g*, and supposing, as in § *i*, (§ 105), A and C to be equal, there will be no difference between A and C, and consequently *d* (§ *g*.) will be equal to 0. Equation § *g*, will then give us sine *s* = 2 sine $\frac{1}{2}$ *s* cos. $\frac{1}{2}$ *s*; and (§ *i*.)

§ *n*. Cos. *s* = 2 cos.^{2} $\frac{1}{2}$ *s*.

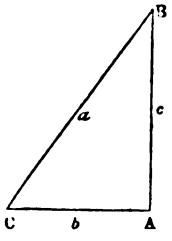
§ 107. In the logarithmic solution of every trigonometric problem, there are two distinct processes to be considered: the first is to establish a formula which shall exhibit the geometrical relations between the data and quæsita, and the other is to arrange a set of numerical tables, as Tables I. and II., pp. 3. 23, in which certain logarithms have been calculated and are registered, and by the use of which the calculations indicated by the formula may be made. What these tables are has already been explained. In arranging the formulæ it often happens

Digitized by Google

that an expression, which will answer when the angle is small, (§ 98. § *l.*) will not answer when the same angle is large.

§ *a.* Hence it often becomes necessary, as indicated at § *i.*, (§ 98.) to adapt the formulæ to the peculiar conditions of the problem. All that is necessary to the arrangement of these formulæ has been already taught both in Geometry and Logarithms. But as the grouping of these formulæ is an important part towards the logarithmic solution of trigonometric problems, it may not be amiss to recapitulate, at least so far as to show clearly what is meant.

§ *b.* Let C A B be a right angled triangle, right angled at A.



1. $\frac{c}{a}$ = sine C (§ 98. § *d.*)
2. $\frac{c}{b}$ = tang. C (§ 98. § *e.*)
3. $\frac{b}{a}$ = cos. C (§ 98. § *i.* 4).
4. $\frac{b}{c}$ = cot. C (§ 98. § *i.* 5).
5. $b^2 + c^2 = a^2$ (§ 43.)

§ *c.* The right angle being always known from the conditions of the triangle, and one of the acute angles (§ 32. § *d.*) being the complement of the other, it is necessary to consider only four of the six parts (§ 106.) of a right angled triangle, viz., the three sides and one of the acute angles. *The foregoing equations* (§ *b.*) *or formulæ are sufficient for the solution of every problem in right angled Plane Trigonometry,* (§ 75. § *e.*)

§ *d.* Thus if the two sides be given, and the hypothenuse or either angle be required:

1. (§ *b.* 5.) $a = \sqrt{c^2 + b^2}$—and logarithmically (§ 80. and § 97. § *c.*) $a = \frac{1}{2}(c^2 + b^2)$.

To find the angle C:

2. (§ *b.* 2.) tang. C $= \frac{c}{b}$; and by logs. (§ 80.) tang. C = log. c — b.

§ *e.* Given the hypothenuse a, and one leg, c.

To find the other leg b, and either acute angle C.

1. $b = \sqrt{a^2 - c^2}$.

To find the angle C:

2. (§ *b.* 1.) sin. C $= \frac{c}{a}$, and log. sin. C = log. c — a.

§ *f.* Given the hypothenuse a and one angle C.

To find the two legs c and b:

1. (§ *b.* 1, and § XLI. § *a.*) $c = a \times$ sin. C; and log. c = log. a + sin. C.

To find b:

2. (§ *b.* 3. and § XLI. § *a.*) $b = a \times$ cos. C, and log. b = log. a + cos. C.

§ *g.* Given either side, c, and an angle C.

Digitized by Google

To find the hypothenuse a:

1. (§ b. 1.) $a = \frac{c}{\text{sin. C}}$; and log. a = log. c — sin. C.

To find the leg b:

2. (§ b. 2.) $b = \frac{c}{\text{tang. C}}$; and log. b = log. c — tang. C.

This group of formulæ may be still further extended, so as to include other trigonometric functions, as cosines, secs., co-secs., cotangs., or their equivalents (§ 98. § l.).

§ h. If the triangle involved be oblique (any one of the angles (§ 32. § b.) being the supplement of the other two,) the value of at least three of five parts, viz., two angles and three sides—must be given in order to solve the problem, and at least one of these three parts must be a side.

§ 108. The several combinations therefore of three, which can be formed of five, comprise all the cases that are necessary for solving trigonometric problems.

§ a. To one of these every problem in plane trigonometry resolves itself for solution.

§ b. These several combinations are reduced to *five* cases; viz.,

1st, When two sides and the angle which is opposite to either of them, are given:

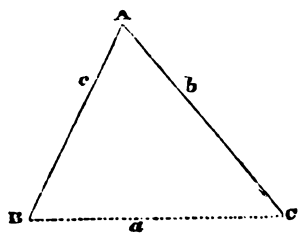
2d, When two angles and the side which subtends either of them, are given:

3d, When two sides and the angle which they contain, are given:

4th, When two angles and the side that is between them, are given:

5th, When the three sides are given.

CASE I.



§ 109. Given the sides (c and b) and the angle (B), that is opposite to (b) one of them:

c = 450 yards.
b = 600 yards.
B = 74° 49′

Required the remaining parts (A, C, and a)?

§ a. First, to find the value of C. By § 74., b : sine B : : c : sine C; and substituting for these given parts (b, c, and C), their values, the proportion is: 600 : sine 74° 49′ : : 450 : sine C.

Log. sine of 74° 49′ = 9.984569
Logarithm of 450 = 2.653213

12.637782
Logarithm of 600 = 2.778151

Log. sine C = 9.859631 = 46° 22′ 15″.

Digitized by Google

§ *b.* The sum of the two angles B and C (§ 32. § *b.*) being subtracted from 180°, gives the remaining angle (A) of the proposed triangle A B C. Thus B + C = 121° 11′ 15″ — 180° = 58° 48′ 45″ = A.

§ *c.* The logarithmic process (§ *a.*) of finding the value of C, might have been abbreviated, and the operation might have been performed entirely by addition.

§ *d.* This abbreviation (§ 101.) consists in using the arithmetical complement of the logarithm of the first term in the order of proportion, in the place of said logarithm.

§ *e.* This arithmetical complement, added to the logarithm of the second and third terms, gives the logarithm, (rejecting 10 from the index,) of the fourth or required term.

§ *f.* Let it be borne in mind that the *arithmetical complement* (§ 88. § *d.*) *of any numerical expression, is obtained, by subtracting the expression proposed, from the number which is made by prefixing unity* (1) *to as many cyphers, as there are figures in said expression.* Thus the arithmetical complement of 89 is 11, for 89 — 100 = 11. Or, the arithmetical complement is obtained by beginning at the left, and subtracting each figure from 9 (§ 79. § *c.*), except the last significant figure, which must be subtracted from 10. Thus the arithmetical complement of 9.984569 is 0.015431 (what the former wants of 10.000000), and is obtained thus:

	9.9 9 9 9 9(10)
Logarithm	9.9 8 4 5 6 9
Ar. co.	0.0 1 5 4 3 1

§ *g.* And the arithmetical complement of 3.450000 (§ *f.*) is 6.550000, and is obtained thus:

	9.9(10)0 0 0 0
Logarithm	3.4 5 0 0 0 0
Ar. co.	6.5 5 0 0 0 0

§ *h.* When the logarithmic index of any of the *trigonometric functions exceeds* 9, the arithmetical complement of such index is the difference between itself and 19, (§ 89. § *d.*) and consequently the arithmetical complement is found by subtracting said *index* from 19. Thus the logarithmic tangent of 74° is 10.542504, and its arithmetical complement is 9.457496, which is the co-tang. of 74°.

	1 9.9 9 9 9 9(10)
74° log. tang.	1 0.5 4 2 5 0 4
Ar. co.	9.4 5 7 4 9 6

Digitized by Google

§ *i*. To find the value of the side *a*; according to § 74. sin. B : *b* : : sin. A : *a*; or, substituting their values, sin. 74° 49′ : 600 : : sin. 58° 48′ 45″ : *a*.

Log. sine 74° 49′ ar. co. = 0 015431 = co-sec. B (§ 100. § *a*.),
Logarithm 600 - = 2.778151
Log. sine 58° 48′ 45″ = 9.932208

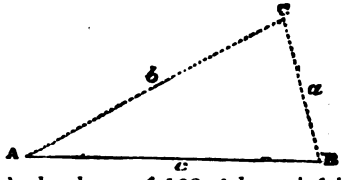
Log. *a* = 2.725790 = 531.8 yards.

The 10, which was borrowed for the arithmetical complement of the logarithmic sine of 74° 49′, being rejected in the sum, gives 2 for the index of the logarithmic value of *a*.

§ *j*. In the solution of all trigonometric problems by calculation, the *logarithmic* values of the functions employed are always used; therefore the repetition of the word log. before sine, tangent, etc., will be omitted; and the arithmetical complement of the logarithm of a function or number, is that which is to be understood, and not the arithmetical complement of the number itself.

CASE II.

§ 110. Given two angles (A and C) and the side (*c*) that subtends one of them.



A = 23° 56′
C = 76° 4′
c = 1760 feet.

To find the other parts (B, *a* and *b*).

§ *a*. The process of solution in this case is a repetition of the methods shown § 109. § *b*. and § *i*.; for A + C subtracted from 180° (§ 32. § *b*.) gives B = 80°; and (§ 74.) sine C : *c* : : sin. A : *a* : : sin. B : *b*.

§ *b*. To find *a*. Sin. 76° 4′ : 1760 : : sin. 23° 56′ : *a*.

Sine 76° 4′ ar. co. = 0.012970 = co-sec. C (§ 101. § *b*.)
Log. 1760 = 3.245513
Sine 23° 56′ = 9.608177

Log. *a*. = 2.866660 = 735.6 feet.

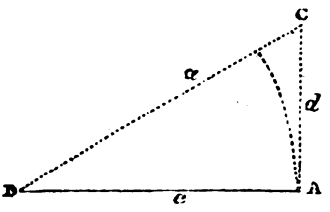
§ *c*. To find *b*. Sin. 76° 4′ : 1760 : : sin. 80° : *b*.

Sine 76° 4′ ar. co. = 0.012970 = co-sec. C
Log. 1760 = 3.245513
Sine 80° = 9.993352

Log. *b*. = 3.251835 = 1785.8 feet.

Digitized by Google

§ *d*. If, with similar data, the proposed, be a right angled triangle, the problem may be solved as the one above is, by means of the proportion between the sides and sines of opposite angles; or it may be solved by means of the principles involved (§ 75.) in the proportion between the sides and trigonometric functions of a right angled triangle. Thus, the data being,



$C = 67° 19'$
$c = 1760$ feet.

The proposed triangle is right angled at A; therefore the value of A is known (D A C). To find the other parts (D, *d* and *a*),

§ *e*. The third angle (D) is *always* known (§ 32. § *b*.) by subtracting the sum of the two other angles from 180°; A + C — 180° = D, or 22° 41′.

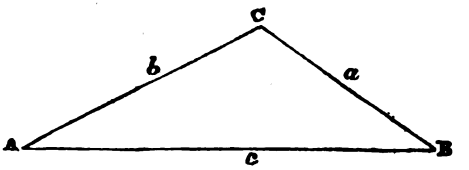
§ *f*. To find the two sides *a* and *d*; making D A radius, the following proportions (§ 75. § *c*.) are deduced, viz:

Rad : *c* : : tang. D : *d*; and Rad. : *c* : : sec. D : *a*.

Radius (*always*, § 98. § *m*.)	= 10.000000	
c = 1760 log.	= 3.245513	
D = 22° 41′ tang.	= 9.621142	
Log. *d*	= 2.866655	= 735.6 feet.
Radius	= 10.	
c = 1760 log.	= 3.245513	
D = 22° 41′ sec.	= 0.034963	
Log. *a*	= 3.280476	= 1907.5 feet.

CASE III.

§ 111. Given two sides (*b* and *a*) and the angle (C) they contain;



$b = 479$ fathoms.
$a = 419.8$ "
$C = 119° 41'$.

To find the other parts, (A, B and *c*.),

§ *a*. The solution of this problem is founded upon § 77.

§ *b*. One angle (C) of the proposed triangle being known, the sum of the two other angles (A and B) (§ 32. § *b*.) is obtained by subtracting the given angle from 180°. Thus, 180° — 119° 41′ = 60° 19′, the sum of A and B.

Digitized by Google

§ *c*. To find the values of A and B; according to § 77., $(b + a) : \text{tang.} \frac{A + B}{2} : : (b \infty a) : \text{tang.} \frac{A \infty B}{2}$. Therefore, by substitution, $898.8 : \text{tang. } 30° 9' 30'' : : 59.2 : \text{tang.} \frac{A \infty B}{2}$.

$(b + a) = 898.8$ log. ar. co. $= 7.046337$
$(A + B) \div 2 = 30° 9' 30''$ tang. $= 9.764207$
$(b \infty a) = 59.2$ log. $= 1.772322$

$$\text{Tang.} \frac{A \infty B}{2} = 8.582866 = 2° 11' 30''.$$

Now half the difference (2° 11′ 30″) between A and B, being added to half their sum (30° 9′ 30″) (§ 78. § *h*.), gives B the greater angle; and being subtracted from said half sum, gives A the less angle. Thus 30° 9′ 30″ + 2° 11′ 30° = 32° 21′, or B; and 30° 9′ 30″ — 2° 11′ 30″ = 27° 58′, or A. A is known to be the less angle (§ 63.), because its subtending side (*a*) is the less of the sides *b* and *a*.

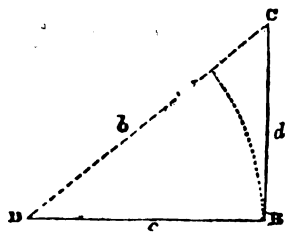
§ *d*. The angles and two sides being known, the value of the third side (*c*) is deducible by means of calculations conducted upon the proportion (§ 74.) between the sides and sines of the angles of plane triangles.

§ *e*. To find *c*. Sin. B : *b* : : sin. C : *c*.

B = 32° 21′ sin. ar. co. = 0.271573 = co-sec. B (§ 100. § *a*.)
b = 479 faths. log. = 2.680336
C = 119° 41′ sin. = 9.938908 (§ 102. § *g*.)

Log. *c*. = 2.890817 = 777.7 faths.

§ *f*. If the problem comprise a right angled triangle, with similar data, the process of solving it is much more simple. For the two legs and the right angle being the given parts, the calculations for determining the unknown parts, are founded upon the relations of the sides and trigonometric functions of a right angled triangle, as pr. § 75.



§ *g*. In the proposed triangle (D B C), right angled at B, the values of the legs are;

c = 479 faths.; and *d* = 419.8 faths.; to find the other parts.

§ *h*. Making either leg (*c*) radius, (§ 75 § *c*.) the terms and order of the proportion for finding the value of D, are, *c* : rad. : : *d* : tang. D. And for finding the hypothenuse (*b*) they are, rad. : *c* : : sec. D : *b*.

Digitized by Google

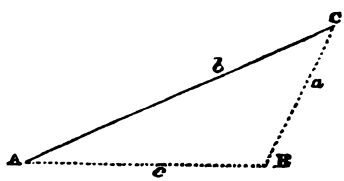
§ *i*. To find D.

$c = 479$. Log. ar. co.	$= 7.319664$
Radius - -	$= 10.$
$d = 419.8$ log.	$= 2.623042$
Tang. D	$= 9.942706 = 41° 13' 53''$.

§ *j*. To find *b*.

Radius - -	$= 10.$
$c = 479$ log.	$= 2.680336$
$D = 41° 13' 53''$ sec.	$= 0.123777$
Log. *b*	$= 2.804113 = 636.9$ faths.

CASE IV.



§ 112. Given two angles (A and C) and the side (*b*) between them;

A = 26° 1′
C = 38° 49′
b = 179 chains.

To find the values of the other parts (B, *c* and *a*) of the proposed triangle (A B C).

§ *a*. Two angles being known, the third (B) (§ 32. § *b*.) is also known; it is B = 115° 10′

§ *b*. The remaining unknown parts (*a* and *c*) of this triangle, are determined by means of the principles involved in the solution of the problem under Case 2. The process of operation in the solution of this, is precisely similar to that of § 109. § 1. under Case 1. In the method of their solution, Cases 1, 2, and 4, are only repetitions of each other. For whenever two angles of a triangle are given, the third is also known (§ 32. § *b*.); and whenever an angle and its subtending side are two of the known parts, the required parts are determinable through calculations conducted upon the proportion (§ 74.) which exists between the sides and sines of angles in all triangles.

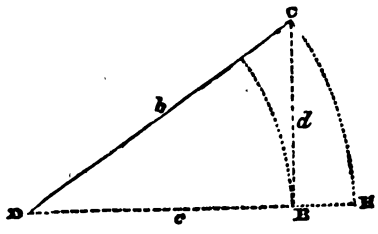
§ *c*. To find the value of *a*. Sin. B : *b* : : sin. A : *a*.

B = 115° 10′, sin. ar. co.	$= 0.043316$ = co-sec. B (§ 101. § *b*.)
b = 179 chains log.	$= 2.252853$
A = 26° 1′, sin.	$= 9.642101$
Log. *a*.	$= 1.938270 = 86.7$ chains.

§ *d*. To find the value of *c*. Sin. B : *b* : : sin. C : *c*.

B = 115° 10′ co-sec.	$= 0.043316$
b = 179 chains log.	$= 2.252853$
C = 38° 49′ sin. -	$= 9.797150$
Log. *c*	$= 2.093319 = 123.9$ chains.

Digitized by Google



§ *e.* Transferring the conditions of this problem to one in right angled trigonometry, the use of sines may be retained in the calculation for determining the unknown parts (*c* and *d*); for by making the given side (*b*), radius to an arc (C H), the two legs of the proposed triangle (D B C) become (§ 75. § *a.*) sine and co-sine to the acute angles (D and C); and (§ 75. § *b.*) rad. : *b* : : sin. D : *d* : : co-sine D : *c*. The parts given are D = 26° 1′, and *b* = 179 chains.

§ *f.* To find the values of *c* and *d*.

Radius - -	= 10.	
b = 179.	log. =	2.252853
D = 26° 1′	sin. =	9.642101
Log. *d.*	=	1.894954 = 78.5 chs.

	Radius	= 10.
b = 179	log.	= 2.252853
D = 26° 1′	cos.	= 9.953599
Log. *c*	=	2.206452 = 160.8 chains.

§ *g.* The same result may be obtained by making a radius of either leg (*c*), and introducing different trigonometric functions into calculation, upon the principles shown under § 75. § *c.* Thus; sec. D : *b* : : radius : *c* : : tang. D : *d*.

§ *h.* To find *c* and *d* by this method of calculation:

D = 26° 1′ sec. (ar. co.)	=	9.953599 = cos. D (§ 101. § *b.*)
b = 179 chains	log. =	2.252853
Radius - - -	=	10.
Log. *c.*	=	2.206452 = 160.8 chains.

D = 26° 1′	cos. (§ 101. § *b.*)	= 9.953599
b = 179 chains	log.	= 2.252853
D = 26° 1′	tang.	= 9.688502
Log. *d.*	=	1.894954 = 78.5 chains.

§ *i.* The use of sine and co-sine as functions in plane trigonometrical calculations, being more convenient than that of other functions, the former (§ *f.*) is generally preferable to the latter method (§ *h.*) of solving problems.

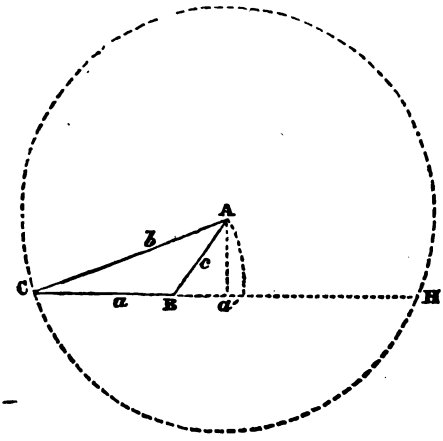
CASE V.



§ 113. Given the three sides (C B, *b c.*)

B C = 144 chains.
b = 220 chains.
c = 103 chains.

To find the angles (C, A and B).

§ *a.* Here is the application to practice of the principles involved in § 79. And in order to determine the value of any one (C) of these angles by calculation, the distance (*a a'*) from the middle (*a*) of the base (C B), to the perpendicular (A *a'*) upon it, must be found by means of the proportion, (§ 79.) the base B C : *b* ∽ *c* : : *b* + *c* : 2 *a a'*. Then either of the segments (C *a'*) is found (§ 79. § *d.*) by applying (C *a*) half the base (C B) to (*a a'*) the distance of the perpendicular at *a'* from the middle of the base. This segment (C *a'*), the perpendicular (A *a'*), and the side (*b*), adjacent to the required angle (C), form a right angled triangle (C A *a'*); of which are known the hypothenuse (*b*) and a leg (C *a'*).

§ *b.* The value of the required angle (C) is then found according to the principles established under § 75. For by making the hypothenuse (C A) radius, the segment (C *a'*) becomes co-sine to the required angle (C); the value of which may then be determined (§ 75. § *b*) by means of the proportion, *b* : radius : : C *a'* : cos. C.

§ *c.* Knowing the value of any one (C) of the angles, either of the others (A) may then be determined by means of calculations conducted upon the proportion (§ 74.) of the sides of triangles to the sines of their opposite angles. And the remaining angle (B) (§ 32. § *b*,) is determinable by subtraction.

§ *d.* To find the value of the angle C.

1st. Call C B the base, in order to find twice the distance (*a a'*) from the middle of the base to a perpendicular drawn upon the base, from its opposite angle (A) (§ 79.). Twice the length of this distance (*a a'*) is evolved by the proportion; C B : *b* ∽ *c* : : *b* + *c* : 2 *a a'*.

C B = 144, log. ar. co. = 7.841637
b ∽ *c* = 117. log. = 2.068186
b + *c* = 323. log. = 2.509203

Log. 2 *a a'* = 2.419026 = 262.4

2d. To find the greater segment C *a'*. One half of 262.4 (2 *a a'*)

Digitized by Google

is equal to the distance ($a\ a'$) of the perpendicular from the middle of the base; and (§ 79. § *d.*) $a\ a' + \frac{B\ C}{2} = C\ a'$. Therefore, 131.2 + 72 = C a' = 203.2.

§ *e.* If twice the distance ($a\ a'$) of the perpendicular from the middle of the base be *greater* than the base, the perpendicular falls *without* the triangle, as in the case before us. But if it be *less* than the base, the perpendicular falls *within* the triangle.

To find the value of C. According to § *b.* we have, *b* : rad. : : C a' : cos. C.

b = 220.	log. ar. co. =	7.657577
Radius	=	10.
C a' = 203.2	log. =	2.307924
Cos. C. =		9.965501 = 22° 32′ 11″

§ *f.* To find the value of A (§ *c.*) we have, *c* : sin. C : : B C : sin. A.

c = 103.	log. ar. co.	= 7.987163
C = 22° 32′ 11″	sine	= 9.583504
B C = 144.	log.	= 2.158363
Sine A		= 9.729030 = 32° 24′ 2″

§ *g.* To find the value of B. According to § 32. § *b.* C + A — 180° = B; therefore B = 125° 3′ 47″.

§ *h.* If, when the perpendicular falls *without* the triangle, the obtuse angle (B) be the first part required, the side (*c*) adjacent to it becomes hypothenuse to the right angled triangle, of which, the perpendicular to the base and the smaller segment (B a') of the base, are legs, and the supplement (A B a') of the required angle (B) is that which is evolved from the proportion (§ *b.*), *c* : rad. : : B a' : cos. A B a'.

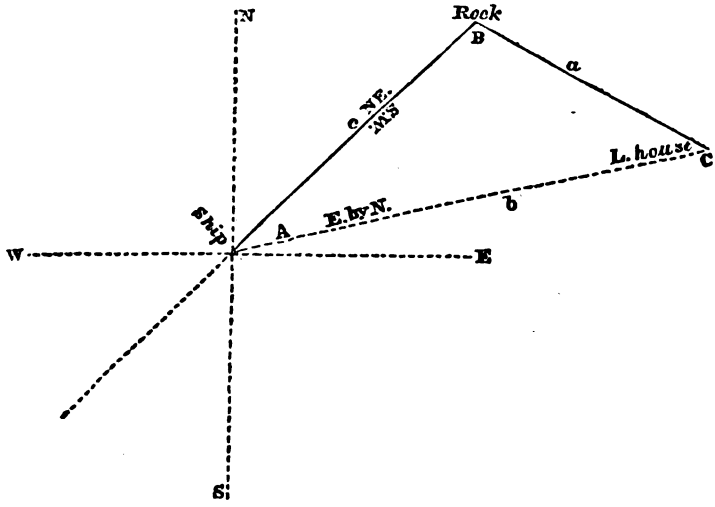
PRACTICAL EXAMPLES.

§ 114. A rock is seven miles from a light-house, and a ship, having the light-house to bear E. by N., is nine miles S. W. of the rock; What is the distance between the ship and the light-house?

Ans. 12.4 miles.

§ *a.* The solution of this problem is conducted after the methods shown under § *a.* and § *i.* (§ 109.) The parts given are the sides *a* and *c*, and the angle (A) contained at the ship, between the bearing of the rock and light-house. The value of A is known by converting into degrees, etc., the points contained between the bearing of the rock and light-house, from the ship. The rock bears N. E., and the light-house E. by N. from the ship. Three points intervene between E. by N. and N. E., and each point contains 11° 15′; therefore the angle (A) contained between the lines of these bearings is 11° 15′ × 3, or 33° 45′.

Digitized by Google

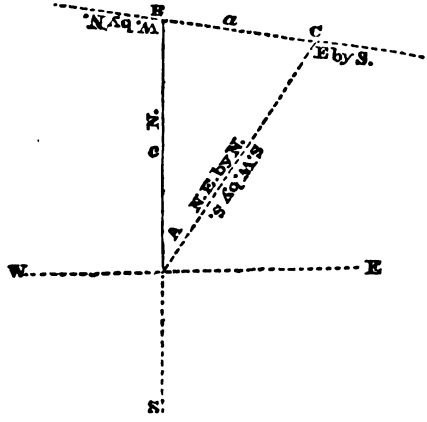


§ *b*. Unless the problem were embraced in a right angled triangle, the value of C must be found, and B known (§ 32. § *b*.) before that of *b* is determined. C is found (§ 109. § *b*.) from the proportion (§ 74.) which exists between certain parts of every triangle; viz., *a* : sin. A : : *c* : sin. C. Then C + A — 180° = B; and then, sin. C : *c* : : sin. B : *b*, affords the solution required.

EXAMPLE II.

§ 115. A ship was steering N. and sailing 10 knots per hour; she made a point of land bearing N. E. by N.; two hours afterwards the same point bears E. by S. What is the distance of it from the ship?

Ans. 12. + miles.



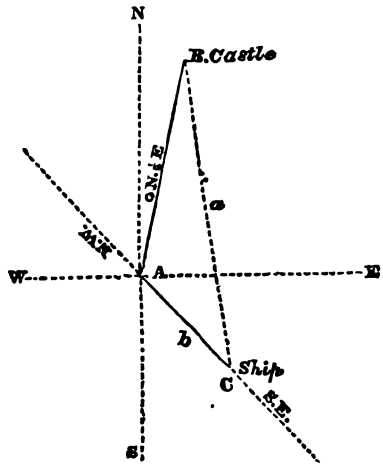
Digitized by Google

§ *a*. The solution of this problem depends upon the principles which Example 1 involves. The angle (A) between the point of land and the ship's course is three points, or 33° 45′. The angle (C) between the bearing of the ship from the point of land at each station, is six points, or 67° 30′. And the angle (B) between the second bearing of the land and the line upon which the ship sailed, is seven points, or 78° 45′; or it is A + C — 180 = 78° 45′. Then the proportion of sin. C : *c* : : sin. A : *a*, determines the value of the part required.

EXAMPLE III.

§ 116. Several boats, intending to cut a ship out from under the guns of a castle, wish to know how far she is off from the castle, which bears N. ½ E. 917 fathoms from a watch-tower, that is 491 fathoms N. W. from the ship.

Ans. 1285.7 fathoms.



§ *a*. The solution of this problem involves in it the principles demonstrated § 77, by which either angle (B or C) is found; and then the length of the required side (*a*) is determined by the ratio between the sides and sines of opposite angles.

§ *b*. The parts given are, the distances (*b* and *c*) of the watch-tower (A) from the ship and castle, and the angle (A) contained at the watch-tower between the lines of bearing from it to the castle and ship. The angle (A) at the watch-tower contains 11½ points, or 129° 22′ 30″. The sum of the angles B and C is found by subtracting A (§ 32.) from 180°. And half their difference is determined by the proportion (§ 77.), $b + c$: tangent $\frac{B + C}{2}$: : $b \sim c$: tang. $\frac{B \sim C}{2}$

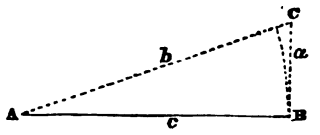
§ *c*. The value of B and of C is then known by § 77. § *h*.; and the solution completed by evolving the value of *a* from the proportion,— sin. C : *c* : : sin. A : *a*.

EXAMPLE IV.

§ 117. Wishing to know the height of a Chinese pagoda that stood in a plane, I took the altitude of the sun from an artificial horizon, and at the same time the length of the shadow cast by the pagoda was marked and measured.

Digitized by Google

The sun's corrected altitude was 21° 10′.
The length of the shadow 347 feet.
Ans. Height of pagoda 134.3 feet.



§ *a*. The pagoda is supposed to stand upright. The angle (A) which is formed at the end of the shadow by an imaginary line drawn thence to the top of the pagoda, is 21° 10′, or whatever be the altitude of the body which causes the shadow. The solution of this problem may be conducted according to the principles shown § 75. § *c*.

§ *b*. The parts given are the length (*c*) of the shadow, the angles A and B. The latter is known from the primitive condition of the triangle, which is right angled.

§ *c*. Making the given leg radius, the other leg (*a*) or height of the pagoda becomes tangent to the angle (A) of altitude. The value of the required part (*a*) is evolved by means of the proportion, rad. : *c* : : tang. A : *a*.

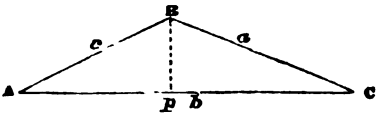
EXAMPLE V.

§ 118. A road crosses a mountain, the base of which is nine miles across. The distance from the foot to the top of the mountain, is 4.5 miles on one side, and 5.3 on the other.

What is the angular ascent of the road on each side of the mountain, and how high is the top above the base?

Ans. Angle of ascent on one side = 21° 32′.
Angle of ascent on the other = 26° 37′.
Height of the mountain 1.94 miles.

§ *a*. This problem involves in the solution of it, the principles demonstrated § 79. and § 75. The parts given are the three sides (*a*, *b*, *c*).



§ *b*. The operation for finding the ascent of the road, or the angles A and C, is a repetition of the method shown in Case 5, § 113, for finding C and B. B *p*, the perpendicular upon the base (*b*) of the mountain, shows its height; the value of it is determined (§ 75.) after the angles A and C are determined. A C : $c \infty a$: : $c + a$: $2p\,b$; and (§ 79. § *d*.) $p\,b + \frac{A\,C}{2} = p\,C$; and (§ 75. § *b*.) *a* : rad. : : *p* C : cos. C; and (§ 74.) *c* : sin. C : : *a* : sin. A; and rad. : *a* : : sin. C : B *p*.

EXAMPLE VI.

Wishing to ascertain the breadth of a river, I observed that a cocoanut tree, which stood at the water's edge on the opposite bank, bore

Digitized by Google

west of me; then after having walked due south 194 yards, the same tree bore N. W.

How wide was the river?

Ans. 194 yards.

EXAMPLE VII.

Wishing to know the height of a mountain in South America, on the morning of the 22d December, 1832, between eight and nine o'clock, I measured with a sextant the altitude of the sun above the top of the mountain; it was 19° 40′ 15″. The apparent altitude of the sun, measured at the same time from an artificial horizon, was 41° 47′ 45″. Then going from the mountain, I measured 4420 fathoms, and the next day, when the top of the mountain was again in the plane of the sun's azimuth circle, the sun's altitude above the top of the mountain, and from an artificial horizon taken as before, was, from the horizon = 40° 21′ 30″, above the mountain, = 25° 14′.

What is its height?

Ans. 3564.1 fathoms, or 21384 feet 7 inches.

EXAMPLE VIII.

Supposing that a ray of light is not refrangible, that the earth is a perfect sphere, that its diameter is 7924 miles,* and that the height of Chimborazo is 21384 feet, How far can the top of this mountain be seen from the surface of the earth?

* The mean diameter of the earth is about 7923.57 miles.

SPHERICS.

§ 119. Spherical Trigonometry is one of the principal branches upon which the science of navigation is founded. The solution of all problems for finding latitude, longitude, variation, etc., from data obtained by means of observations made upon celestial objects, depends upon the principles of spherical trigonometry.

§ *a.* As the figure of the earth is an approximation to that of a sphere, the whole science of navigation, properly speaking, is based upon the doctrines of the sphere.

§ 120. The figure of a *sphere* may be generated by the revolution of a semicircle about its diameter, as an axis. A perfectly round globe or ball is a sphere.

§ 121. Trigonometrically speaking, all lines upon a sphere are curved lines. These lines are either circles or arcs of circles. Circles are either *great* or *small.*

§ 122. A *great circle* is concentric with the sphere. The plane, therefore, of every great circle will pass through the centre of the sphere, and divide the sphere into two equal parts. Moreover, if three great circles be drawn on a sphere, their planes will all intersect at the centre, which is a common point, and divide the sphere into eight spherical triangles.

§ *a.* If a line be drawn perpendicularly through a plane, it will form right angles with every line which it crosses in that plane.

Thus, imagine a line drawn from the zenith to the nadir: it will be perpendicular to the plane of the horizon. Now, if we imagine any number of lines, as those corresponding to all points of the compass, to be drawn through the point where this line from the zenith cuts the plane of the horizon, said line will form right angles with all the rest.

The shortest distance between two points on a plane (§ 3.) is the straight line that joins them; and the shortest distance on a sphere, between two points, is the arc of a great circle, that joins them.

§ *b.* Every great circle has two *poles.*

§ 123. The *poles* of a great circle are two points on the surface of a sphere, that are diametrically opposite to each other, and are equidistant from all points at the circumference of their circle. Consequently each pole is 90° from the circumference of its circle.

§ *a.* The north and south poles are the poles of the equator. The equator is 90° from either pole.

§ 124. The straight line, which, passing through the centre of a great circle, joins its poles, is the *axis* of that circle.

Digitized by Google

§ 125. All great circles cross each other in points diametrically opposite. Therefore,

§ *a*. Two great circles cannot be parallel; but they divide each other into arcs of 180° each.

§ *b*. The space contained between the intersecting halves of two great circles is called a *lune*.

§ 126. One great circle is perpendicular to another, when the two cross each other at right angles.

§ *a*. When two great circles cut each other at right angles, the axis of either lies along the plane of the other; and they pass through the poles of each other.

§ 127. A *secondary* is a great circle that crosses another perpendicularly.

§ *a*. A meridian of longitude is secondary to the equator.

§ 128. Every great circle divides its sphere into two equal parts, as the Equator does the earth.

§ 129. A *small circle* divides the sphere into two unequal parts, as the Tropic of Cancer, or of Capricorn, or as a parallel of latitude does the earth.

§ *a*. If every point at the circumference of a small circle be equidistant from either pole of a great circle, the small is parallel to the great circle.

§ *b*. The centre of a small circle is in the axis of the great circle to which it is parallel.

§ 130. The radius of a small circle, is the sine of the arc intercepted between its circumference and the pole of the great circle, to which it is parallel.

§ *a*. The radius of a parallel of latitude is the co-sine of its own latitude. Therefore the rad. of a parallel of latitude is the co-sine of its own latitude; and since (§ 76. § *e*.) circles or arcs of circles are to each other as their radii, we establish the two propositions, viz:

§ *b*. The length of an arc of a circle at the equator, or the number of miles to a degree at the equator is to the length of a mile, or the number of miles to a degree in any latitude, as radius is to the cos. of that lat., or sin. co-lat.

§ *c*. And also the length of a degree in one latitude is to the length of a degree in another, as cos. the one lat. is to cos. the other.

§ 131. All spheric, like all rectilinear, angles, are either acute, right, or obtuse; and their values are expressed under the same denominations, as of degrees (°), minutes (′), and seconds (″).

§ 132. Two arcs of great circles, like two straight lines, (§ 25 and § 27.) that cross each other, make the vertically opposite angles equal to each other, the two angles that are on the same side of either, equal to two right angles, and the four angles together equal to four right angles.

§ 133. A spherical angle is at the pole of the circle, upon which it is measured.

§ *a*. And the arc of this circle, which is intercepted between the two arcs forming the angle, is its measure. Thus the angles which two meridians make with each other, are at the north and south poles, and

Digitized by Google

the arc of the equator which is intercepted between said meridians, and subtends the given angle, measures that angle.

This arc of the equator also measures (§ 49. § *e.*) the angle contained at its centre between two lines drawn from the centre to the extremities of said arc. And these two lines would lie, one in the plane of each meridian, and contain the angle which the two meridians make with each other. Therefore

§ *b.* The angles which the planes of two great circles make with each other, are the angles at which the circles themselves intersect. And if a third plane be thrust through the two others, *perpendicularly* to their line of intersection, it will cut each of these two planes perpendicularly, and show their angle of intersection.

§ *c.* The two circles which form an angle are secondaries (§ 127.) to the great circle upon which the angle is measured, and therefore the latter passes through the poles (§ 126. § *a.*) of its secondaries.

§ *d.* The distance between the poles of two intersecting great circles, also measures the angles at which they cross each other. Thus, take the meridians of 40° W. and 20° E.: the arc of the equator between them is 60°. They therefore (§ *a.*) make an angle of 60° at the pole. And since the pole of each (§ 123.) is 90° from its circle, one pole of the meridian of 40° W. would be in long. of 130° W., (40 + 90 = 130,) and one pole of the other meridian would be in 70° W., (20° E. — 90 W. = 70° W.,) and 130° W. — 70° W. = 60°, which is the angle of intersection, and the distance of the poles of these two meridians.

§ *e.* If therefore the poles of any three circles whose arcs form a triangle, be connected by arcs of great circles, we shall have what is called the "polar triangle" to the first triangle; the angles of this polar triangle (§ *d.*) will be respectively equal to the supplement of the sides of the first triangle, and the sides of the polar triangle will be also respectively equal to the supplement of the angles of the first triangle.

§ 134. Every spherical, like every plane triangle, has three sides and three angles, and any two of the former are greater than the third.

§ 135. The sides of a spherical triangle are arcs of circles. Their values are *always* expressed in degrees (°), minutes (′) and seconds (″).

§ 136. Plane triangles are unlimited as to the value of their sides; but the sum of the three sides of a spherical triangle is less than 360°. For if two arcs that form an angle be each 180°, they will intersect each other (§ 125.) in another point, that is diametrically opposite to their angular point; then, if a third arc cross these two, it will divide the lune (§ 125. § *b.*) into two triangles, and be a side to each. This third side is less (§ 134.) than the sum of the two other sides of either triangle, and the sum of these four sides, by supposition, is two semicircles, or equal to 360°; therefore the sum of the two sides of either triangle plus the third side, is *less* than 360°; and so with any spherical triangle.

§ *a.* The minimum of the sides of a spherical triangle is without limits.

§ 137. The sum of the angles of a plane triangle is equal to two right angles; but the sum of the angles of a spherical triangle, in all cases, is greater than two, but less than six, right angles.

§ *a.* The exterior angle of a spherical triangle (§ 132.), therefore is

Digitized by Google

not, as in a plane triangle, necessarily equal to the sum of the two remote interior angles of the triangle.

§ *b.* Most of the other propositions of elementary geometry which show the ratio, relations, or equality between the parts of plane triangles, are likewise applicable to spherical triangles.

§ 138. Two angles, or two legs of a spherical triangle, are *alike*, or of the *same affection*, when both of them are either acute or obtuse.

§ 139. In spherical, as in plane triangles (§ 63.), the greatest side and angle subtend each other; so also do the mean and the least.

§ *a.* An angle and its opposite side are not always of the same affection.

§ 140. Spherical, besides being, as plane triangles, divided into equilateral, isosceles, and scalene, are either right angled, quadrantal, or oblique.

§ 141. A *right angled spherical triangle* has one right angle.

§ *a.* The side subtending the right angle is the hypothenuse; but it is not, as in a plane triangle, necessarily the greatest side.

§ *b.* If the hypothenuse be less than 90°, the legs are of the same affection; and the oblique angles also.

§ *c.* If the hypothenuse be greater than 90°, the legs are unlike, and the oblique angles also.

§ *d.* A leg of a right angled spherical triangle, and its opposite angle, are always of the same affection.

§ *e.* The sides of a spherical triangle being arcs of circles, each side is measured (§ 49. § *e.*) by the angle which it subtends at the centre of the sphere.

§ 142. A *quadrantal triangle* has a side that is a quadrant, or 90°.

§ 143. An *oblique spherical triangle* has neither a side, nor an angle equal to 90°.

§ 144. In plane triangles, the sides, and the sines of their opposite angles, have the same ratio to each other; but in spherical triangles, the sines of the opposite sides and angles are proportional.

§ 145. In plane triangles (§ 107.), one side, at least, must be among the three parts that constitute the data necessary for finding the other parts; but in spherical triangles, any three parts are data sufficient for determining the other parts. Therefore—

§ 146. In spherical trigonometry, the three sides of a triangle can be determined by having the three angles as data; and the reverse.

§ 147. For the purpose of facilitating by logarithmic calculation, the solution of problems that are included in oblique triangles, spherical trigonometry is here divided into right and oblique angled trigonometry.

§ *a.* All the problems that come under the several cases, two excepted, of oblique spherical trigonometry, may be solved by reducing them to analogous cases in right angled trigonometry; this is done by means of drawing a perpendicular from an angle upon its subtending side, of the proposed triangle, and from such an angle, that the proposed oblique triangle will be divided into two right angled triangles, one of which shall contain two of the parts given in the problem.

Digitized by Google

§ 148. Every problem in oblique trigonometry may be solved without the direct intervention of a perpendicular.

§ *a*. The process of calculation is shortened by solving the problems without conducting the operation upon the principles of right angled triangles. For this reason spherical trigonometry is here divided into right and oblique trigonometry.

§ 149. Problems comprising as data the three angles, or the three sides of an oblique triangle, do not admit of the intervention of right angles for determining the unknown parts; because, in neither case can a perpendicular be so drawn in the proposed triangle, that two of the given parts will fall in either of the right angled triangles, or on either side of the perpendicular.

§ 150. By some, problems that depend upon quadrantal triangles, are included in a separate division of spherical trigonometry, called "quadrantal trigonometry." But knowing three parts, the other three of a quadrantal triangle may be determined by the rules for finding with similar data, like parts that are unknown in a right angled triangle.

§ *a*. In arranging for calculation the trigonometric functions of the parts in a problem included in a quadrantal triangle, the legs must be called *angles*, and their adjacent angles, *legs*; the *supplement* of the angle that subtends the quadrantal side, must be called the *hypothenuse*, and the quadrantal side, *radius*.

§ 151. The side and angle that are opposite in a quadrantal triangle, are of the same affection.

§ 152. The relations between the parts of a triangle in plane, and the parts of a triangle in spherical trigonometry, are similar; and the formulæ for the solution of problems in the one, are analogous to the formulæ for the solution of similar problems in the other.

§ *a*. As much, with regard to the sides, can be determined from the three angles of a plane triangle, as can be determined from the three angles of a spherical triangle. In the former case, the triangle can be determined in *species*; and in the latter, the sides are determined in degrees and minutes of arcs, and these degrees and minutes only express the proportion (§ 50. § *e*.) which the arcs bear to the entire circumference of their circles, without any regard to the *absolute* length of those arcs; for they may be infinitely great or infinitely small. The number of miles or of any units, of linear measure contained in an arc of a spherical triangle, is determined according to the length of the semi-diameter of the circle of which the arc is a part, just as the absolute length of the three sides of the supposed plane triangle is determinable from the length of some other line,—as of the radius of the circumscribed or inscribed circle,—which has a known relation to the given triangle.

§ *b*. In order, therefore, to arrive at absolute values for sides of spherical triangles, a third quantity, that will answer the purpose of a common measure for lines and arcs, must be brought into consideration.

§ *c*. And this common measure is the *semi-diameter* of a circle. When we say that a side of a spherical triangle is an arc containing a certain number of degrees and minutes, we have no reference to the *absolute* length of this arc, or to the number of inches, or fathoms, or

Digitized by Google

miles contained in it. It may be an arc whose radius is infinitely great or small. But if the length of its radius in inches, or miles, be known, the *absolute* length of the arc also in the denominations of the same dimensions is determinable. But this subject belongs to another branch of mathematics, which is not relevant to the purposes for which this treatise is designed.

§ 153. The analogy between the formulæ for the solution of problems of like data and quæsita in plane and spherical trigonometry, grows out of the resemblance between the parts of a plane and a spherical triangle.

§ *a*. Suppose that the sides of a spherical triangle should remain of the same *absolute* length, and that the radius of their sphere be increased *ad infinitum*. The angles at the centre of the sphere, which these sides subtend, and the number of degrees contained in these sides, or arcs, will be decreased until they reach the *ultimatum*, when the surface included by these three sides becomes a plane, the triangle a plane triangle, and a *finite* portion of infinity.

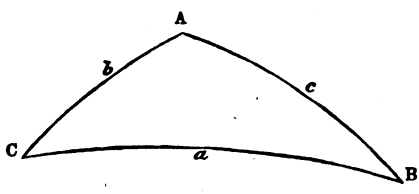
RIGHT ANGLED SPHERICAL TRIGONOMETRY.

§ 154. In the trigonometrical solution of right angled spherical triangles, there are *five parts*, (three sides and two angles,) any one of which may be the unknown and required part of the problem.

§ *a*. The right angle is ever known from the condition of the triangle. In calculation the right angle is not called a *part*.

§ *b*. Any two of the five parts of a right angled spherical triangle being known, the rest are determinable by means of trigonometrical calculations.

Therefore in every right angled spherical triangle there are five *parts*, any two of which—the right angle being always known by the conditions of the problem—are sufficient to determine the rest. Let A C B be a spherical triangle, right angled at A. Now as every problem comprises at least three parts, two given and one required, it follows that there are as many cases for demonstration as there are combinations of three from five. There are therefore ten combinations. Now if we take a separate diagram to show the relations in each combination between the two known and each of the three unknown parts of the triangle, there would seem to be thirty illustrations required to embrace every problem that can occur. Only ten, however, can occur, and the rest are repetitions of these ten. And these ten may be reduced to six cases by stating them in general terms. Thus, where the parts given are in combination, in general terms,



Digitized by Google

1. a and b,	the hypothenuse and a leg,	
2. a and c,	they make	case 1.
3. a and B,	the hypothenuse and an angle,	
4. a and C,	they make	case 2.
5. b and c,	the two legs	case 3.
6. B and C,	the two angles,	case 4.
7. B and b, 8. C and c,	an angle and its opposite leg,	case 5.
9. c and B, 10. b and C,	a leg and its adjacent angle,	case 6.

Combinations 1 and 2, 3 and 4, 7 and 8, and 9 and 10, are similar, but as they are not *identical*, it will require ten demonstrations to prove that every problem in right angled spherical trigonometry must come within certain rules that apply to every case that can occur.

§ *c*. And, by a most happy artifice, Lord Napier, Baron of Murchison, has given two simple rules which comprehend every case that can occur, and by one or the other of which every problem in right angled spherical trigonometry may be readily solved. They are known as comprising what is called the "Catholic Proposition," which relates to the "circular parts."

§ *d*. The *circular parts* are the two legs, the *complement* of the hypothenuse and of each of the two angles. Therefore, by Napier's rules, we deal with these complements instead of with the hypothenuse and the two angles themselves.

§ *e*. The right angle (§ 154. § *a*.) is thrown out of consideration; and the five circular parts join each other.

§ *f*. The complement of the hypothenuse joins the complement of each of the two angles; each of which angular complements joins its adjacent leg, and the two legs join each other.

§ *g*. In every problem two of these parts are given and a third is sought. They are named from their relative position with regard to each other.

One of them is the *middle* part; the two others are *extremes*, either *conjunct* or *disjunct*.

§ *h*. If the parts given and the part sought join each other in circular order, the first and last in this order are called *extremes conjunct*; and the part between them connects them together, and is called the *middle* part.

§ *i*. The triangle A B C, (p. 110,) represents a right angled spherical triangle, right angled at A; its hypothenuse is a, its two legs b and c. The circular parts are the leg b, the complement of C, do. of a, do. of B, and the other leg c.

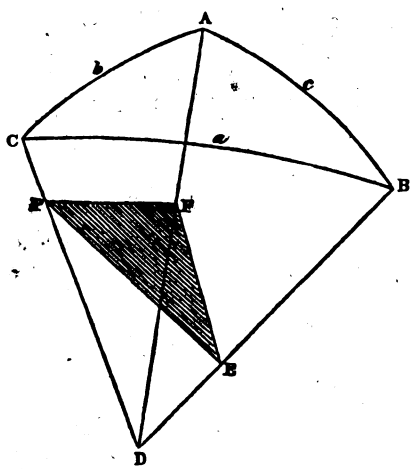
§ *j*. The three parts, a, B, c, join in circular order. The complement of B is the connecting part between c and the complement of a. The complement of B is the middle part; c, and the complement of a, are extremes conjunct.

Digitized by Google

Of the parts.	The middle part is,	The extremes conjunct are,
1. B, *c*, *b*.	*c*.	*b*, and complement of B.
2. *c*, *b*, C.	*b*.	*c*, and complement of C.
3. *b*, C, *a*.	Complement of C.	*b*, and complement of *a*.
4. C, *a*, B.	Complement of *a*.	Complements of C and B.
5. *a*, B, *c*.	Complement of B.	*c*, and complement of *a*.

§ 155. Imagine A B D C to be a solid section of a sphere made by the planes of three great circles (§ 122.), whose intersected arcs *a*, *b*, and *c*, are the sides of the spherical triangle A B C, right angled at A. This triangle is represented in the figure with the plane C D B of the hypothenuse *a* resting upon the paper and coinciding with its surface. C D A is the plane of leg *b*, and B D A of leg *c*.

§ *a*. These planes (§ 122.) all pass through the centre D of the sphere, and make the same angles with each other (§ 133. § *b*.) that their arcs make with each other. That is: the angle which the plane of *b* makes along D C (which represents the line of meeting of the two planes) with the plane of *a*, is equal to the angle C. Also the angle along the line D A which the plane of *b*. and the plane B D A of *c* make with each other is equal to the spherical right angle A which the two arcs *b* and *c* make with each other. Also the spherical angle at B which the arcs *a* and *c* make with each other is the same as that which their planes make along their line B D of intersection.



§ *b*. Now if from any point as E in the line B D made by the intersection of the planes of *c* and *a*, a line E F be drawn in the plane of *c*, and perpendicular to the aforesaid line B D,—and if also a plane be inserted along this perpendicular E F, and at right angles to the plane of *c*—it will cut from the figure under consideration a solid triangle D E F P, which has four faces, each presenting a plane right angled triangle. There being four triangles and but six sides among them, every side is common to two of the triangles.

§ *c*. The plane of the face P F E, being by construction (§ *b*.) perpendicular to the line D B, which is common (§ *a*.) to the planes of *a* and *b*, it is perpendicular to each of those planes. The angle F E P, is then the angle which the planes of these two arcs make with each other, and (§ 133. § *b*.) is therefore equal to the spherical angle B.

§ *d*. Likewise because the plane of the face P F E is perpendicular to the plane of *c*, and because also the planes of *b* and *c* are at right

Digitized by Google

angles—(they form the spherical angle A, which, by construction, (§ 155.) is a right angle)—the angle D F P which the said plane P F E makes in the plane of *b* with the line D F is also a right angle.

§ *e*. Also, because the face P F E of the solid triangle D E F P, is, by construction (§ *b*.) perpendicular to the plane of *c*, which again is perpendicular to the plane of *b*, the angle E F P, made by these two perpendiculars on the face P F E, is a right angle.*

§ *f*. Now recapitulating the angles that are known on each of the faces of the solid triangle D E F P, we have:

1. On the plane of *c* (§ *b*.) the right angle	D E F
2. On the plane of *b* (§ *d*.) the right angle	D F P
3. On the plane of *a* (§ *b*,) the right angle	D E P
4. On the face P F E (§ *c*.) the right angle	E F P
5. On the face F E P (§ *c*.) = spherical angle	B

Upon the relations of the trigonometric functions of these four plane triangles, is based the whole system of spherical trigonometry; and these relations are established by means of the principles demonstrated under Propositions X. and XI. (§ 74. and § 75.), and treated of again in the chapter on Logarithms under § 98. and § 107. Applying, therefore, the principles on which that beautiful theorem is founded, to each, successively, of the four plane right angled triangles exhibited on the several faces of the solid triangle of the figure, and then combining the results, we shall be led to the demonstration of each one of the 10 problems derived (§ 154. § *b*.) from the six cases there stated in right angled spherical trigonometry. We shall moreover show by these demonstrations the application of one or the other of Napier's rules to each one of the two combinations, and thus, by a separate demonstration for each particular combination, establish the general application of those remarkable rules.

§ *g*. They assert that the sine of the middle part is equal to the tangents of extremes conjunct (§ 154. § *j*.), and

§ *h*. That it is also equal to the cosines of extremes disjunct (§ 154. § *l*.)

§ 156. As the six cases (§ 154. § *b*.) embrace all the ten combinations that can occur, and as there are three problems under each of these cases, in all eighteen problems, we shall establish Napier's rules (§ 155. § *g*. and § *h*.) by means of ten (§ 155. § *f*.) separate demonstrations, and show their application to each of these eighteen problems, eight of which (§ 154. § *b*.) are repetitions of some of the other ten.

* The student who has not the aid of an instructor to assist him with these diagrams and their demonstrations, may perhaps find some of the difficulties removed by using solid diagrams made of wood. Take for instance a piece of soft pine and shape it with a knife into a *right angled* prism. Then taper off each face equally until the prism be pointed, the right angle being preserved to the point in which the three sides meet. Now with this point as a centre and with any convenient radius, describe an arc on each of the three tapering sides of the prism. This arc will represent the sides of a right angled spherical triangle; and the planes, the solid section of a sphere as represented in the diagram. With the figure thus constructed, the other lines as sines, etc. may also be drawn on the wood.

Digitized by Google

§ *a*. It should be borne in mind that whenever the value of two of three quantities which constitute a problem be known, the other (§ XXXVIII. § *a*.) is also known. Thus, if we establish the proposition that the cos. two legs = cos. hypothenuse, or cos. *b* cos. *c* = cos. *a*, it is immaterial which one of these parts be the quæsitum of the problem, provided the other two be known. For it is evident that cos. *c* is the log. difference between cos. *a* and cos. *b*, or that cos. *b* is the log. difference between cos. *a* and cos. *c*.

§ *b*. Therefore when we establish an equation for the three parts of a problem, the problem will be proved, whichsoever of the three be the unknown part. We shall therefore always assume two parts to be known, and shall name them because it gives a more convenient expression for the problem.

CASE I. (§ 154. § *b*.)

§ 157. When the hypothenuse and a leg, as *a* and *b*, are given, the other parts are the two angles B and C, and the other leg *c*, either of which (§ 154. § *b*.) may be the object of the problem. And

Problem 1. *When the other leg, c, is required.*

DEMONSTRATION I.

§ *a*. Let C A B be the proposed spherical triangle, right angled at A, constructed and lettered in all respects as under § 155.

§ *b*. With D P as rad. in the triangle D F P (§ 155. § *d*.) on the plane (§ 155.) of *b*; Cos. *b* (§ 98. § *d*.) = $\frac{\text{D F}}{\text{D P}}$.

§ *c*. With D F as rad. in the triangle D E F on the plane of *c*; Cos. *c* (§ 98. § *a*.) = $\frac{\text{D E}}{\text{D F}}$.

§ *d*. And for the same reason, in the triangle D E P on the plane of *a*, with D P for Rad.; Cos. *a* = $\frac{\text{D E}}{\text{D P}}$.

§ *f*. Now multiplying the first two equations (§ *b*. and § *c*.), we have cos. *c*. cos. *b* = $\frac{\text{D E}}{\text{D F}} \times \frac{\text{D F}}{\text{D P}} = \frac{\text{D E}}{\text{D P}}$ = (§ *d*.) cos. *a*.

§ *g*. But the complement of *a* (§ 155. § *d*.) is the circular *part;* and (§ 52. § *d*.) cos. *a* = sine of its complement. It is the middle part, (§ 154. § *n*. 5) *b* and *c* are extremes disjunct. Wherefore—

§ *h*. In this problem cos. extremes disjunct = sine middle part.

Problem 2. *When the opposite angle,* B, *is required.*

DEMONSTRATION II.

§ *i*. In the right angled triangle E F P, F E P (§ 155. § *c*.) is equal

Digitized by Google

known, and shall name them because it gives a more convenient expression for the problem.

CASE I. (§ 154. § *b*.)

§ 157. When the hypothenuse and a leg, as *a* and *b*, are given, the other parts are the two angles B and C, and the other leg *c*, either of which (§ 154. § *b*.) may be the object of the problem. And

Problem 1. { *When the other leg, c, is required.*

DEMONSTRATION I.

§ *a*. Let C A B (p. 114) the proposed spherical triangle, right angled at A, be constructed and lettered in all respects as under § 155.

§ *b*. With D P as rad. in the triangle D F P (§ 155. § *d*.) on the plane (§ 155.) of *b*; Cos. *b* (§ 98. § *d*.) $= \frac{D\,F}{D\,P}$.

§ *c*. With D F as rad. in the triangle D E F on the plane of *c*; Cos. *c* (§ 98. § *a*.) $= \frac{D\,E}{D\,F}$.

§ *d*. And for the same reason, in the triangle D E P on the plane of *a*, with D P for Rad.; Cos. *a* $= \frac{D\,E}{D\,P}$.

§ *f*. Now multiplying the first two equations (§ *b*. and § *c*.), we have cos. *c*. cos. *b* $= \frac{D\,E}{\cancel{D\,F}} \times \frac{\cancel{D\,F}}{D\,P} = \frac{D\,E}{D\,P} =$ (§ *d*.) cos. *a*.

§ *g*. But the complement of *a* (§ 155. § *d*.) is the circular *parts* and (§ 52. § *d*.) cos. *a* = sine of its complement. It is the middle part, (§ 154. § *n*. 5) *b* and *c* are extremes disjunct. Wherefore—

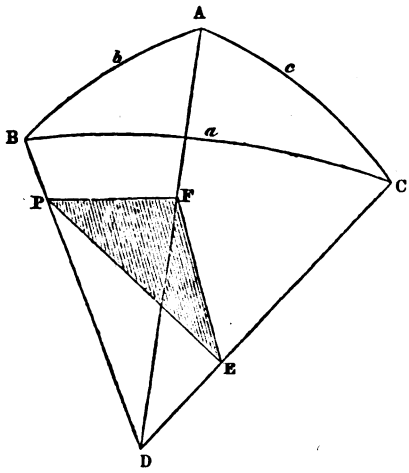
§ *h*. In this problem, cos. extremes disjunct = sine middle part.

Problem 2. { *When the opposite angle,* B, *is required.*

DEMONSTRATION II.

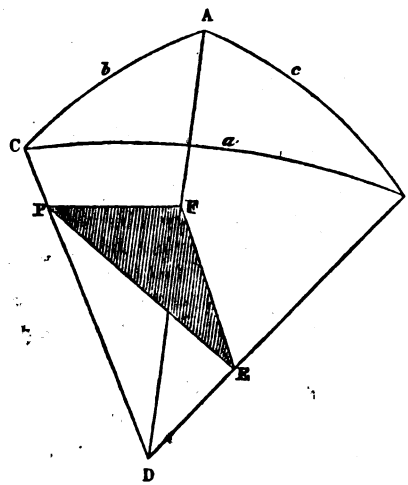
§ *i*. In the right angled triangle E F P, F E P (§ 155. § *c*.) is equal to the spherical angle B. And with E P as rad., sin. F E P = B = is equal (§ 98. § *d*.) to $\frac{P\,F}{E\,P}$. And for the same reason in the triangle D E P sin. *a* $= \frac{E\,P}{D\,P}$.

Digitized by Google



§ *j*. So also in the triangle D F P. Sin. $b = \frac{P\ F}{D\ P}$.

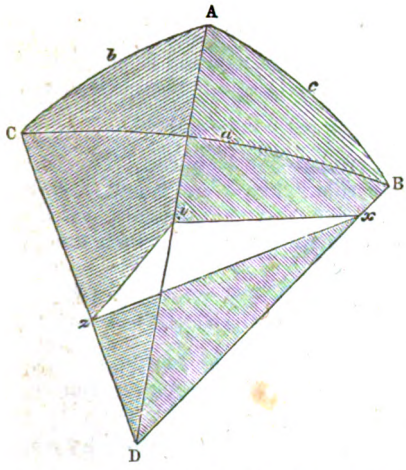
§ *k*. Now multiplying the equations under (§ *i*.), we have sine B × sine $a = \frac{P\ F}{E\ F} \times \frac{E\ F}{D\ P} = \frac{P\ F}{D\ P} = (\S j.)$ sine *b*. The complements of B and *a* (§ 154. § *d*.) are the circular parts, and the cos. of their complements (§ 52. § *d*.) is the sine of the arc and angle themselves. Exactly in the same way (if *c* had been the given leg, and C the angle sought), using sine C and sine *c* in the place of sine B and sine *b*, it may be proved that sine C × sine *a* = sine *c*.



§ *l*. Now in this problem, the complements of *a* and B (§ 154. § *n*. 4.) are extremes disjunct, and *b* the middle part. Wherefore the rule, cosines of extremes disjunct are equal to the sine of the middle part, is proved to apply here also.

Prob. 3. { § *m*. When the contained angle C is required: instead of inserting the intersecting plane along the line F E, perpendicularly to the planes of the two arcs *c* and *a*, as at § 155., so as to make the angle F E P equal to the

Digitized by Google



spherical angle B, let it intersect the line C D at z perpendicularly to the planes of b and a, so as to make the angle $y\ z\ x$ equal to the spherical angle C (§ 133. § b.) which these two arcs contain, as in the figure opposite.

§ n. The several faces of the solid triangle $z\ y\ x$ D thus made, will then, according to the principles of construction shown under § 155, present the following right angled plane triangles, viz:

1. On the plane of a, the triangle $x\ z$ D, right angled at z.
2. On the plane of b, the triangle D $z\ y$, right angled at z.
3. On the plane of c, the triangle D $y\ x$, right angled at y.
4. On the plane of $x\ y\ z$, a triangle right angled at y.
5. Also in the same plane and triangle, the angle $y\ z\ x$ (§ m.) = C.

DEMONSTRATION III.

§ o. Now with the triangle $x\ z$ D on the plane of a, and (§ n. 1) right angled at z, if we make $x\ z$ rad., we have (§ 98. § c. and § 98. § i. 5) cot. $a = \frac{\text{D}\ z}{x\ z}$.

§ p. Also, in the right angled (§ n. 2) D $z\ y$, on the plane of b, if we consider D z as rad. we shall have (§ 98. § e.) tang. $b = \frac{z\ y}{\text{D}\ z}$.

§ q. Now if we multiply these two equations by each other, we shall have tang. $b \times$ cot. $a = \frac{z\ y}{\text{D}\ z} \times \frac{\text{D}\ z}{x\ z} = (\S\ \text{XII. § } b.)\ \frac{z\ y}{x\ z}$.

§ r. But $z\ y$ and $x\ z$ (§ 155. § b.) are also sides of the right angled (§ n. 4) triangle $x\ y\ z$; and (§ 98. § d.) $\frac{z\ y}{x\ z}$ = cos. $y\ z\ x$. But (§ n. 5) $y\ z\ x$ is equal to the spherical angle C. Wherefore $\frac{z\ y}{x\ z}$ = cos. C.

§ s. Now (§ g.) tang. $b \times$ cot. $a = \frac{z\ y}{x\ z}$. Wherefore tang. b cot. a = cos. C. But (§ 154. § j. 3) complement of C is the middle part; b and complement a are extremes conjunct—also (§ 52. § d.) cot. a = tang. Co. a, and cos. C = sine Co. C. Wherefore tang. $b \times$ tang. Co. a = sine Co. C, or "tangents of extremes conjunct equal sine mid. part."

Digitized by Google

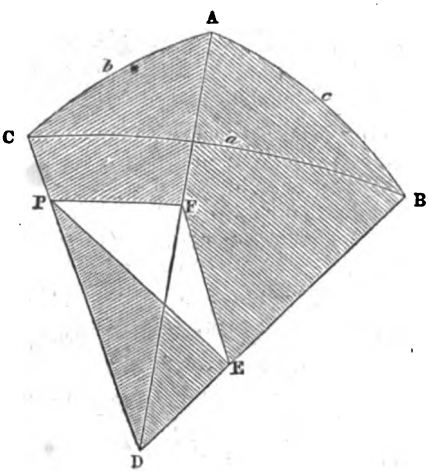
CASE II. (§ 154. § *b*.)

§ 158. When the hypothenuse and an angle, as *a* and B, are given, the problems are with regard to the other angle C, and the two legs, *b* and *c*.

Problem 4. { When the containing leg *c* is concerned.

This and Problem 3 are similar, but not identical. The former proves the application of Napier's rule, when *a* and *b* and *their* contained angle C are involved; the latter requires it, when *a* and *c* and *their* (the other angle) contained angle are concerned, which combination of parts is only similar, not identical.

DEMONSTRATION IV.



§ *a*. Let the diagram be constructed and lettered as at § 155. Then (§ 155. § *c*. and § 98. § *e*.) tang. $c = \frac{EF}{DE}$, and, (§ 98. § *i*. 5) cot. $a = \frac{DE}{PE}$

§ *b*. Multiplying these two equations by each other, we have tang. $c \times$ cot. $a = \frac{EF}{DE} \times \frac{DE}{PE} = \frac{EF}{PE}$ (§ XII. § *b*.)

§ *c*. But (§ 155. § *c*. and § 98. § *d*.) $\frac{EF}{PE} =$ cos. B.

Wherefore tang. $c \times$ cot. $a =$ cos. B. But, (§ 154. § *j*. 5.) *c* and complement of *a* are extremes conjunct, and complement of B is the middle part; by (§ 52. § *d*.), sin. complement B = cos. B. Also tang. complement *a* = cot. *a*. Hence tang. *c* tang. co. *a* = sin. co. B; which is Napier's rule.

§ *d*. The *circular* parts of the hypothenuse and of the two angles (§ 154. § *d*.) are their complements. Let it therefore be understood henceforward that when the sign (co.) is affixed to a letter, its complement or *circular* part is meant.

§ *e*. Thus, sin. a^{co}, sin. B^{co}, tang. C^{co} may be understood to mean, sin. complement of *a*, sin. co. B, tang. co. C, etc.

§ *f*. With this explanation and § 54. § *d*., it will be perceived, how that the expressions tang. or sin. a^{co}, tang. or sin. B^{co}, and tang. or sin. C^{co}, are the equivalents of cot. or cos. *a*, cot. or cos. B, cot. or cos. C, —*a* being understood to mean the hypothenuse of a right angled spherical triangle, B and C its two oblique angles.

Problem 5. { § *g*. When the opposite leg *b* is comprised, making the three parts of the problem, *a*, B and *b*, which are

Digitized by Google

those of Prob. 2. These two problems are therefore identical, and the application of the rule is already proved.

Problem 6. { § *h*. When the other angle C enters the problem, the parts are *a*, B and C, being the same as those of Problem 12. Those two problems are identical: see

therefore the demonstration under the latter, in which it is proved tang. $B^{co} \times$ tang. $C^{co} =$ sin. a^{co} (§ *d*.) or tangents extremes conjunct = sin. middle part.

CASE III. (§ 154. § *b*.)

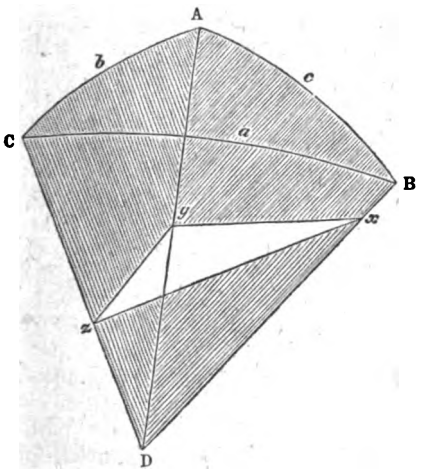
§ 159. When the two legs, as *b* and *c*, are the parts given, the complements of the other three parts, as *a*, B and C, form the three problems.

Problem 7. { § *a*. When the angle C enters the problem, making (§ 154. § *j*. 2) C^{co} and *c* extremes conjunct, and *b* the mid. part. To prove tangents extremes conjunct

equal sine mid. part:

DEMONSTRATION V.

§ *b*. Let the triangle be constructed and lettered as in Problem 3, (§ 157. § *m* and *n*.) Then in the plane triangle *x y z*, right angled at *y* (§ 157. § *n*. 4) by construction, cot. $y\,z\,x$ (§ 98. § *i*. 5) $= \frac{y\,z}{y\,x}$. But (§ 157. § *m*.) $y\,z\,x =$ C. Wherefore cot. C, or (§ 158. § *f*.) tang. $C^{co} = \frac{y\,z}{y\,x}$.



§ *c*. D *z y* (§ 157. § *n*. 2) is the right angle in the triangle on the plane of *b*. And (§ 98. § *d*.) sine $b = \frac{y\,z}{D\,y}$.

§ *d*. Also D *y x* is the right angled triangle (§ 157. § *n*. 3) on the plane of *c*. Wherefore (§ 98. § *e*.) tang. $c = \frac{y\,x}{D\,y}$.

§ *e*. Multiplying the first and last of these three equations together, we have tang. $C^{co} \times$ tang. $c = \frac{y\,z}{y\,x} \times \frac{y\,x}{D\,y} = \frac{y\,z}{D\,y}$ (§ XII. § *b*.). But (§ *c*.) sine $b = \frac{y\,z}{D\,y}$. Therefore tang. C^{co} tang. $c =$ sine *b*.

§ *f*. But (§ 154. § *j*. 2) C^{co} and *c* are extremes conjunct, and *b* the mid. part. Whence the application of Napier's rule (§ *a*.) to this problem.

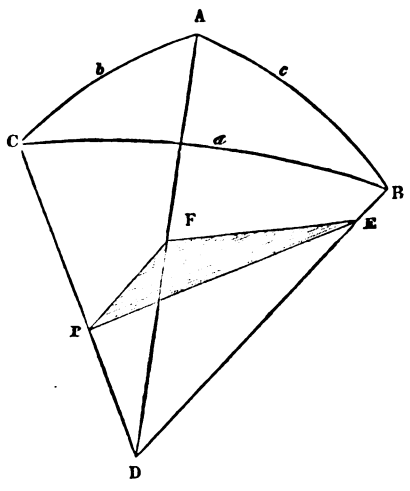
Digitized by Google

Problem 8. { § *g*. To prove its application when the other angle, B, enters the problem, making (§ 154. § *j*. 1) *c* the middle part, *b* and B^{co} (§ 157. § *d*.) extremes conjunct.

This and Problem 7 are similar, but not *identical*, because the parts are not exactly the same. It will therefore require a separate demonstration to prove that in this problem also tang. extremes conjunct = sine mid. part.

DEMONSTRATION VI.

§ *h*. Let the diagram be constructed and lettered as at § *a*. (§ 158.) so as to show the angle F E P (§ 155. § *c*.) which the planes of *b* and *c* make with each other, equal to the spherical angle B, formed by these two arcs. Now applying here the principles used in the preceding demonstration, we perceive that cot. F E P, or its equal B = $\frac{F E}{P F}$; and (§ 158. § *f*.) cot. B = tang. B^{co}, and that therefore tang. B^{co} = $\frac{F E}{P F}$. The principles of demonstration V. applied here, also show how it is that tang. *b* = $\frac{P F}{D F}$; and that these two equations,



multiplied together, give the formula, tang. B^{co} × tang. *b* = $\frac{F E}{P F} \times \frac{P F}{D F} = \frac{F E}{D F}$ = (§ 98. § *c*.) sine *c*. And that, therefore Napier's rule: tang. extremes conjunct = sine middle part, also applies to this problem.

Prob. 9. { § *i*. a^{co} is the remaining part under Case 3.

Therefore the parts of this problem are a^{co}, *b* and *c*, which are the parts of problem 1, to which the application of the rule cos. extremes disjunct = sine mid. part, has already been proved.

CASE IV. (§ 154. § *b*.)

§ 160. When the two angles B and C are the parts given, the other three circular parts *b*, *c* and a^{co}, comprise the three problems.

Problem 10. { § *a*. When leg *c* makes the problem, *c* and B^{co} (§ 154. § *n*. 3) become extremes disjunct, and C^{co} the mid. part. To prove that in this problem cos. extremes disjunct = sine mid. part:

Digitized by Google

DEMONSTRATION VII.

§ *b*. It has already been proved (§ 157. § *f*.) cos. *c* cos. *b* = cos. *a*, which by transposition (§ XLI.) becomes cos. $c = \frac{\text{cos. } a}{\text{cos. } b}$.

§ *c*. And (§ 157. § *k*.) sine B, or (§ 158. § *d*.) cos. $B^{co} = \frac{\text{sine } b}{\text{sine } a}$. Multiplying these two equations together, we have cos. *c* × cos. $B^{co} = \frac{\text{cos. } a \text{ sine } b}{\text{cos. } b \text{ sine } a}$, or which is the same thing, $\frac{\text{cos. } a}{\text{sine } a} \times \frac{\text{sine } b}{\text{cos. } b}$. But (§ 98. § *m*. 7) $\frac{\text{cos. } a}{\text{sine } a}$ = cot. *a*, and (§ 98. § *m*. 1) $\frac{\text{sine } b}{\text{cos. } b}$ = tang. *b*. Wherefore cos. B^{co} cos. *c* = cot. *a* tang. *b*.

§ *d*. Now, (§ 157. § *s*.) cot. *a* tang. *b* = sine C^{co} (cos. C). Therefore cos B^{co} cos. *c* = sine C^{co}. Q. E. D.

Problem 11. { § *e*. When the other leg *b*, makes the problem, *b* and C^{co} (§ 154. § *n*. 1.) become extremes disjunct, and B^{co} the middle part. This and the last problem are similar, for in general terms, each embraces a leg and the two angles; but they are not *identical*, for in the former case, one leg as *c*, and in the latter the other leg as *b*, enters the problem. The demonstrations, though precisely similar, are not identical—and therefore, according to the plan here pursued, a separate demonstration will be given to prove that in this problem also, cos. extremes disjunct = sin. mid. part, or cos. *b* × cos. C^{co} = sin. B^{co}, which is identical with Prob. 15, (§ 161. § *g*.) See therefore Demonsration x. (§ 161. § *h*.) by which that problem is proved to come within Napier's rule.

Problem 12. { § *f*. When the hypothenuse *a* enters the problem: a^{co} (§ 158. § *d*.) is (§ 154. § *j*. 4.) the mid. part, B^{co} and C^{co} extremes conjunct. To prove therefore that in this problem, the tangs. of extremes conjunct, = sin. mid. part—or tang. C^{co} × tang. B^{co} = sin. a^{co}, we have the following

DEMONSTRATION VIII.

§ *g*. It has been proved (§ 159. § *e*.) sin. *b* = tang. C^{co} tang. *c*. And, (§ 98. § *m*. 1.) tang. $c = \frac{\text{sin. } c}{\text{cos. } c}$. Wherefore sin. *b* = $\frac{\text{tang. } C^{co} \cdot \text{sin. } c}{\text{cos. } c}$. Or, (§ XLI.) sin. *b* cos. *c* = tang. C^{co} sin. *c*.

§ *h*. It has also been proved (§ 159. § *h*.) sin. *c* = tang. B^{co} tang. *b*, and (§ 98. § *m*. 1.) that tang. $b = \frac{\text{sin. } b}{\text{cos. } b}$. Hence sin. *c* = $\frac{\text{tang. } B^{co} \text{ sin. } b}{\text{cos. } b}$; or, (§ XLI.) sin. *c* cos. *b* = tang. B^{co} sin. *b*.

§ *i*. Now, multiplying together the last equations under § *g*. and § *h*., we have:

Sin. *b* cos. *c* sin. *c* cos. *b* = tang. C^{co} sin. *c* tang. B^{co} sin. *b*, which

Digitized by Google

by elimination (§ XII. § *b*.) becomes cos. *c* cos. *b* = tang. C^{co} tang. B^{co}.

§ *j*. But (§ 157. § *f*.) cos. *c* cos. *b* = cos. *a*. Therefore (§ 158. § *f*.) cos. *a* or sin. a^{co} = tang. C^{co} tang. B^{co}. The latter (§ *f*.) are extremes conjunct, and the three parts are identical (§ 158. § *h*.) with the three parts of Problem 6. Hence the rule : tangents of extremes conjunct = sin. mid. part, is proved with regard to this as well as to that problem.

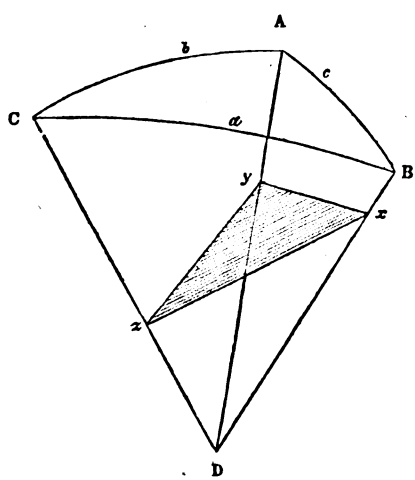
CASE V. (§ 154. § *b*.)

§ 161. When an angle and its opposite leg are given. The given parts therefore may be either B and *b*, or C and *c*. Suppose that *a* be the required part. The three parts of each problem, will be a^{co} *b* and B^{co}, or a^{co} *c* and C^{co}. These two problems are therefore only similar, not identical. According to the plan pursued in like cases, as at Prob. 4, (§ 158. § *a*.) at Prob. 8 (§ 159. § *g*.) and Prob. 11, (§ 160. § *e*.) a separate demonstration is required for each. If the parts be a^{co} B^{co} and *b*, this combination has already occurred twice, viz., at Probs. 2 and 5, and the problem has been proved to come within the rule; but, if the parts be a^{co} C^{co} and *c*, a special demonstration is required; for though the parts in each problem be in all respects similar, such a combination of the *identical* parts is nowhere to be found among the problems stated.

Problem 13. { § *a*. We therefore add a demonstration to prove that, when the problem is comprised of C, *c* and *a*, — (§ 154. § *n*. 2.) cos. C^{co} cos. a^{co} = sin. *c*; or cos. extremes disjunct = sin. mid. part.

Let the diagram be constructed and lettered as at § *m*. § *n*. (§ 157.)

DEMONSTRATION IX.



§ *b*. In the triangle *x y z*, right angled (§ 157. § *n*. 4) at *y*, sine *y z x* (§ 98. § *d*.) $= \frac{x\,y}{z\,x}$. By construction (§ 157. § *n*. 5) *y z x* = C, and (§ 158. § *d*.) sine C = cos. C^{co}. Therefore cos. $C^{co} = \frac{x\,y}{z\,x}$.

§ *c*. In the right angled triangle (§ 157. § *n*. 1) *x z* D on the plane of *a*, cos. $a^{co} = \frac{z\,x}{D\,x}$.

§ *d*. Multiplying together the last equation of § *b*. and the equation of § *c*. we have

Digitized by Google

cos. C^{co} × cos. a^{co} = $\frac{x\,y}{*\,y}$ × $\frac{*\,y}{D\,x}$ = $\frac{x\,y}{D\,x}$ = sine c (§ 157. § *n.* 3, and § 98. § *d.*). Wherefore cos. extremes disjunct = sine mid. part.

§ *e.* For the other two problems under this case, let the given parts be the angle B, and its opposite leg *b*.*

Problem 14. § *f.* When *c* enters the problem, it is the middle part; (§ 154. § *j.* 1,) B^{co} and *b* are extremes conjunct. This problem is identical with Prob. 8, to which it has already been proved (§ 160. § *j.*) that Napier's rule of "tangents conjunct" applies.

§ *g.* When the other angle C enters the problem, it makes the parts C^{co} and *b* disjunct, and B^{co} the middle part, which are the parts of Prob. 11. These two problems are therefore identical, and the rule of "cos. disjunct" (§ 160. § *e.*) remains to be proved.

DEMONSTRATION X.

Problem 15. § *h.* It has already been proved (§ 157. § *f.*) cos. *b* cos. *c* = cos. *a*. Hence (§ XLI.) by transposition we obtain cos. *b* = $\frac{\text{cos. } a}{\text{cos. } c}$ Also (§ 161. § *d.*) cos. $C^{co.}$ = $\frac{\text{sin. } c}{\text{sin. } a}$.

§ *i.* Multiplying these two equations together, we have the expression:

Cos. *b* cos. $C^{co.}$ = $\frac{\text{cos. } a \text{ sin. } c}{\text{cos. } c \text{ sin. } a}$ = $\frac{\text{cos. } a}{\text{sin. } a}$ × $\frac{\text{sin. } c}{\text{cos. } c}$. But (§ 98. § *m.* 7.) $\frac{\text{cos. } a}{\text{sin. } a}$ = cot. *a*, or (§ 158. § *e.*) tang. $a^{co.}$. Also (§ 98. § *m.* 1.) $\frac{\text{sin. } c.}{\text{cos. } c}$ = tang. *c*. Wherefore cos. *b* cos. C^{co} = tang. a^{co} tang. *c*. Now it has been proved (§ 158. § *b.*) tang. a^{co} tang. *c* = sin. B^{co}. Therefore cos. *b* cos. C^{co} = sin. B^{co}, or cosines disjunct = sin. middle part.

CASE VI. (§ 154. § *b.*)

§ 162. When a leg as *b*, and its adjacent angle C are given. This case, like the preceding, (§ 161.) would also admit of a double set of problems, as when the other leg *c* and its adjacent angle B are given. But each of the three problems arising from B and *c* as data, have already been proved to come under the rules. Thus when the problem consists of the three parts B and *c*, with *b*, it is identical with Probs. 8 and 13, demonstration 6. When it consists of B and *c* with *a*, it

* Were the other leg and angle, *c* and C, taken as the given parts, the two other problems to be proved by them, with *b* and B, would be repetitions of problems 10 or 16, and 8.

Digitized by Google

becomes identical with Prob. 4. And when it consists of B and c with C, it becomes identical with Prob. 10, demonstration 7.

§ *a*. We shall therefore consider this case to present only three problems, as when b and its adjacent angle C are given.

Problem 16. { § *b*. When the hypothenuse, as a, enters the problem, making the parts b and a^{co} (§ 154. § *j*. 5) conjunct: to prove that tang. extremes = mid. part. This and Prob. 3 are identical, and the demonstration is the same.

Problem 17. { § *c*. When the other leg c enters the problem, it makes it identical with Prob. 7.

Problem 18. { § *d*. When the other angle B is brought into the problem, then it consists of the three parts B^{co} b, and C^{co}, which is Prob. 10, and to which it has already been proved that Napier's rules apply.

§ 163. We have thus proved, by ten separate demonstrations, that one or the other of Napier's rules applies to every problem that can occur in right angled spherical trigonometry.

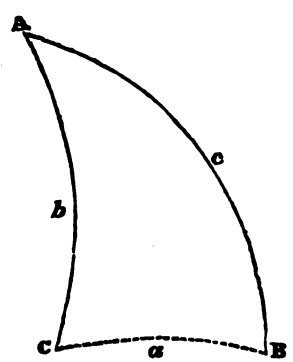
§ 164. We have enumerated among the 18 foregoing problems, eight equations, which are mere repetitions. This was done, however, that the student might be exercised in each formula, and be led clearly to comprehend what was meant (§ 154. § *b*.) as to the three problems under each one of the "six cases."

§ 165. It is important to fix these two rules in the memory, and as a means of doing so, they have been stated in the following mnemonic form:

§ 166. The product of radius and middle part's sine
Equals that of the tangents of parts that combine;
§ *a*. Or, that of the co-sines of those that disjoin.

§ 167. The ten equations which we have demonstrated as falling under these rules, are all suited to logarithmic calculation. And as radius (§ 98.) is the linear unit of the logarithmic system, it does not appear in the formulæ. We get rid of it in the calculation by rejecting it from the log. index of the second member of the equation.

§ *a*. Bearing this in mind, we proceed to illustrate the "six cases" by examples.



§ 168. If the data and quæsita be opposite sides and angles, the problem proposed may be solved by the proportion (§ 144.) between the sines of opposite sides and angles. (*Vide* § 179. p. 131.)

§ 169. A B C represents a right angled spherical triangle upon a plane; B is the right angle, and b the hypothenuse.

§ *a*. The circular parts (§ 154. § *d*. and § *f*.) commencing with c, and naming around to the right, in the order in which they join, are c, a, C^{co}, b^{co} and A^{co}.

Digitized by Google

CASE I.

§ 170. Given the hypothenuse b, and a leg as c, viz:
The hypothenuse $b = 74° 40'$.
The leg $c = 60° 14'$.
To find the other parts, as at Problems 1, 2 and 3 (§ 157.).

§ *a*. 1st. To find the other leg a.

The three parts of this problem, are therefore the two legs (a and c), and the complement of the hypothenuse b^{co}; therefore, (§ 158. § *d*.), b^{co} (§ 154. § *b*.), is the middle part, c and a extremes disjunct. Wherefore (§ 157. § *f*.) cos. a cos. c = sin. b^{co}; or, co-sines disjunct = sin. mid. part. Cos. a is the unknown part, and we find its value (§ XXXVIII. § *a*.) by transposition.

§ *b*. Thus (§ XLI.) $\cos. a = \frac{\sin. b^{co}}{\cos. c}$

Cos. c, 60° 14′ (ar. co.) = 0.304108 (= sec. c. § 98. § *n*. 1.)
Sin. b^{co} (§ 158. § *e*.) = cos. b 74° 40′ = 9.422318
Cos. a, 57° 49′ = 9.726426

§ *c*. In looking in the tables for the degrees, etc., which correspond to the logarithmic co-sine, 9.726426, it will be seen that 122° 11′, the supplement of 57° 49′, also corresponds to it. Which of the two to take, is known (§ 141. § *b*.) by the affection of the two legs.

§ *d*. The sine, tangent, secant, etc., of an arc or angle, (§ 52. § *d*.) are the co-sine, co-tangent, co-secant, etc., of the complement of that arc, and (§ 104.) the sine, tangent, secant, etc., of the supplement of the same arc. Therefore, (§ 102. § *d*.) it appears by the Tables also, that—

§ *e*. *Cor*. The logarithmic value of any trigonometric function corresponds to two arcs or angles, viz., an angle and its supplement. Thus, log. sine 9.611576 = 24° 8′, or 155° 52′.

§ *f*. There is generally some circumstance, however, connected with the conditions of the problem, or triangle, under solution, which determines the affection of the required part, and thence the arc required; for each one of the sides and one of the angles of a spherical triangle (§ 136. and § 137.), may be either greater or less than a right angle, or 90°.

§ *g*. To find the value of A. In this case A^{co} is the middle part. It is between, and joins, the two other parts b^{co} and c. Therefore (§ 154. § *h*.) b^{co} and c are extremes conjunct; and, (§ 155. § *g*.) their tangs. = sine mid. part, or (§ 157. § *s*.) tang. b^{co} tang. c = sine A^{co}.

Tang. b^{co} = cot. b, 74° 40′ = 9.438059
c = 60° 14′ tang. = 10.242655
Sine A^{co} (§ 167.) = cos. A = 9.680714 = 61° 21′ 9″.

§ *h*. 61° 21′ 9″, and *not* its supplement, is known (§ 141. § *b*. and § *d*.) to be the required value of the angle A.

Digitized by Google

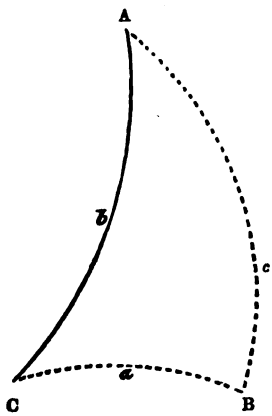
§ *i*. If the angle (C) opposite to (*c*) one of the given sides be required from the data of this case, the ratio (§ 144.) between the sines of opposite sides and angles, will determine the value of it, viz.: Sin. *b* : sin. B (= (§ 169.) rad.) : : sine *c* : sine C.

§ *j*. Or the value of C may be determined by means of the Catholic Proposition; *c* (§ 154. § *l*.) is the middle part, and b^{co} and C^{co} are extremes disjunct; therefore (§ 157. § *k*.) cos. b^{co} cos. C^{co} = sine *c*. But C^{co} is the unknown and required term of the equation. Let us therefore, (§ XL.,) by transposition, arrange the equation so as to present the known quantities all in one member, (§ XXXIX.,) and the unknown in the other member. We shall therefore (§ XLI.) have cos. C^{co} = $\frac{\text{sine } c}{\text{cos. } b^{co}}$.

Cos. b^{co} = sine *b* = 74° 40′ (ar. co.) = 0.015741 = co-sec. (§ 101. § *b*.)
c = 60° 14′ sine = 9.938547

Cos. C^{co} = sine C (§ 141. § *d*.) = 9.954288 = 64° 10′ 14″

CASE II.



§ 171. Given the hypothenuse (*b*) and an angle (C),

b = 119° 39′
C = 104° 01′

To find the other parts.

§ *a*. 1st. To find the other angle (A). The two angles (A, C,) are adjacent to the hypothenuse: b^{co} is therefore (§ 154. § *h*.) the middle part, and the two parts, A^{co} and C^{co}, are extremes conjunct; then (§ 160. § *j*.) tang. C^{co} tang. A^{co} = sine b^{co}. But A^{co} is the required part; and (§ 156. § *a*.) when two parts of the problem are known, the other is determinable. Wherefore (§ XXXVIII. § *a*.) sine b^{co} ÷ tang. C^{co} = tang. A^{co}.

Tang. C^{co} or cot. C = 104° 1′ (ar. co.) = 0.602691 = tang. (§ 100. § *a*.)
Sine b^{co} = cos. *b*, 119° 39′ = 9.694342

Tang. A^{co} = cot. A = 10.297033 = 26° 46′ 36″.

§ *b*. The value of A is known to be less than 90° (§ 141. § *c*.), because C is greater than a right angle.

§ *c*. 2d. To find *a*, which (§ 141. § *d*.) is also less than a right angle: The three parts, *a*, C^{co} and b^{co}, join in circular order; and (§ 154. § *j*.

Digitized by Google

1) C^{co} is the middle part,—b^{co} and a conjunct extremes. Then (§ 157. § *s*.) sine C^{co} = tang. b^{co} tang. a. Wherefore (§ 156. § *a*.) tang. a = sine $C^{co} \div$ tang. b^{co}.

Tang. b^{co} = cot. b = 119° 39′ (ar. co.) = 0.244709 = tang. (§ 101. § *b*.)
Sine C^{co} = cos. C = 104° 1′ = 9.384182

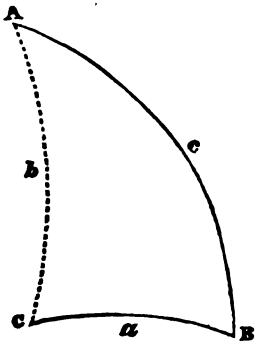
Tang. a = 9.628891 = 23° 2′ 58″.

§ *d*. 3d. To find c; c (§ 141. § *d*.) is greater than a quadrant. The method for finding the value of c in this case, is similar to that (§ 170. § *j*.) of finding C, Case 1. c is the middle part, and (§ 154. § *n*.) the extremes are disjunct; the demonstration of this problem is to be found under § *i*. (§ 157.); where it is proved cos. b^{co} cos C^{co} = sine c, or cos. disjunct = sine mid. part.

Cos. b^{co} = sine b = 119° 39′ = 9.939052
Cos. C^{co} = sine C = 104° 1′ = 9.986873

Sine c = 9.925925 = 122° 31′ 18″.

CASE III.



§ 172. Given the two legs (a, c).
a = 31° 16′
c = 74° 14′
To find the other parts (A, C, b.)

§ *a*. 1st. To find the hypothenuse (b); it is less than a quadrant, because (§ 141. § *b*.) the legs are of the same affection. The three parts, a, b^{co}, and c do not join each other in the circular order; b^{co} stands alone: then (§ 154. § *h*.) a and c are disjunct extremes, and b^{co} is the middle part; therefore (§ 157. § *f*.) cos. c cos. a = sin. b^{co}.

c = 74° 14′ cos. = 9.434122
a = 31° 16′ cos. = 9.931845

Sin. b^{co} = cos. b = 9.365967 = 76° 34′ 12″.

§ *b*. 2d. To find an angle (C); it is less (§ 141. § *d*.) than 90°. The three parts C^{co}, a, c, join in circular order; therefore (§ 162. § *k*.) C^{co} and c, are conjunct extremes, and a is the middle part; then (§ 159. § *e*.) tang. C^{co} tang. c = sin. leg. a; and by transposition, tang. $C^{co} = \frac{\text{sin. } a}{\text{tang. } c}$.

Digitized by Google

$c = 74° 14'$ tang. (ar. co.) $= 9.450777 =$ co-tang. (§ 98. § *n.* 3.)
$a = 31° 16'$ sine $= 9.715186$

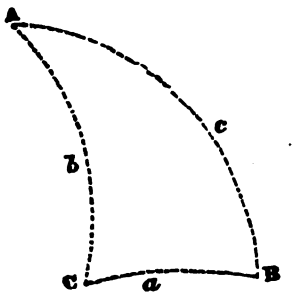
Tang. $C^{co} =$ cot. $C = 9.165963 = 81° 39' 47''$.

§ *c.* 3d. To find the other angle (A); it is also less than 90°, and it is an extreme conjoined to *a* by *c*, which (*c*) is the middle part; then (§ 159. § *h.*) tang. $A^{co} \times$ tang. $a =$ sin. c; and, by transposition, tang. $A^{co} = \frac{\text{sin. } c}{\text{tang. } a}$

$a = 31° 16'$ tang. (ar. co.) $= 0.216659 =$ co-tang. (§ 101. § *b.*)
$c = 74° 14'$ sin. $= 9.983345$

Tang. $A^{co} =$ cot. $A = 10.200004 = 32° 15'$.

CASE IV.



§ 173. Given the two angles (A, C),
$A = 31° 56'$
$C = 111° 11'$
To find the sides *a*, *b*, and *c*.

§ *a.* 1st. To find the hypothenuse (*b*); it is (§ 141. § *c.*) greater than a quadrant; it connects A^{co} and C^{co} in the circular order, which are conjunct extremes; and the problem comes under Demonstration 8 (§ 160. § *g.*), where it is proved that sin. b^{co} = tang. $A^{co} \times$ tang. C^{co}; or tangents conjunct = sin. mid. part.

Tang. A^{co}, or cot. $31° 56' = 10.205336$
Tang. C^{co}, or cot. $111° 11' = 9.588316$

Sin. b^{co}, or cos. $b = 9.793652 = 128° 26' 53''$

§ *b.* 2d. To find the leg *c*; it and A^{co} are extremes disjunct; and when these are the parts of the problem, it has been proved (§ 160. § *d.* and § 161. § *h.*) cos. *c* cos. A^{co} = sin. C^{co}, or co-sines disjunct = sin. mid part. Then, by transposition, cos. $c = \frac{\text{sin. } C^{co}}{\text{cos. } A^{co}}$

Cos. A^{co} or sin. $31° 56'$ (ar. co.) $= 0.276600 =$ co-sec. (§ 98. § *n.* 2.)
Sin. C^{co}, or cos. $111° 11' = 9.557932$

Cos. $c = 9.834532 = 133° 5' 32''$ (§ 189.)

C and *c* (§ 141. § *d.*) are of the same affection.

Digitized by Google

§ *c*. 3d. To find the other leg *a*; it is less than a quadrant, and a disjunct extreme; A^{co} is the middle part; and co-sines disjunct = sin. mid. part. Therefore (§ 159. § *b*. and § 161. § *h*.) cos. *a* cos. C^{co} = sin. A^{co}; and by transposition, cos. $a = \frac{\text{sin. A}^{co}}{\text{cos. C}^{co}}$.

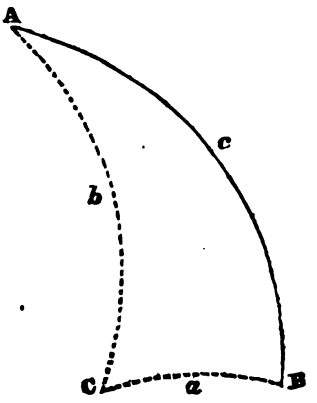
Cos. C^{co}, or sin. 111° 11′ (ar. co.) = 0.030384 = co-sec (§ 101. § *b*.)
Sin. A^{co}, or cos. 31° 56′ = 9.928736

Cos. *a* = 9.959120 = 24° 28′ 18″.

CASE V.

§ 174. Given an angle (C) and its opposite leg (*c*),

c = 45° 19′
C = 54° 49′



To find the other parts (*a*, *b*, A).

§ *a*. This is called the "*doubtful case*," because there is nothing in the condition of any problem that falls under this case, which will determine the affection of the part whose value is sought.

§ *b*. 1st. To find the other leg (*a*); it is the middle part, connecting the conjunct extremes, C^{co} and *c*, whose tangents (§ 159. § *e*.) equal sine *a*, the mid. part.

Tang. C^{co}, or cot. 54° 49′ = 9.848181
c = 45° 19 tang. = 10.004801

Sine *a* = 9.852982 = 45° 27′ 54″.

§ *c*. 2d. To find the hypothenuse (*b*); *b*^{co} and C^{co} are disjunct extremes; and their co-sines, therefore, (§ 157. § *i*. and § 161. § *d*.,) are equal to the sine of the middle part *c*; thus, cos. *b*^{co} cos. C^{co} = sine *c*, and by transposition cos $b^{co} = \frac{\text{sine } c}{\text{cos. C}^{co}}$.

Cos. C^{co}, or sine 54° 49′ (ar. co.) = 0.087612 = co-sec. (§ 101. § *b*.)
c = 45° 19′ sine = 9.851872

Cos. *b*^{co}, or sine = 9.939484 = 60° 27′ 2″.

§ *d*. 3d. To find the other angle (A); it is also (§ 154. § *m*.) disjunct, and with *c* it makes the extremes, whose co-sines (§ 159. § *d*.) = sine

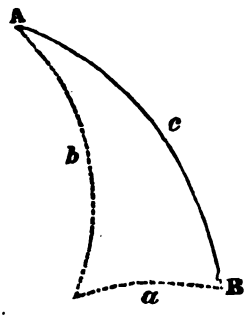
Digitized by Google

C^{co}, or mid. part. Thus, cos. A^{co} × cos. c = sine C^{co} and by transposition cos. A^{co} = $\frac{\text{sine C}^{co}}{\text{cos. } c}$.

c = 45° 19′ cos. (ar. co.) = 0.152929 = sec. (§ 101. § *b*.)
Sine C^{co}, or cos. C 54° 49′ = 9.760569

Cos. A^{co}, or sine A = 9.913498 = 55° 1′ 30″.

CASE VI.



§ 175. Given a leg (c) and its adjacent angle (A),

c = 35° 15′ 7″
A = 74° 47′

To find the values of the other parts (b, C, a),

§ *a*. 1st. To find the value of the hypothenuse (b); it is (§ 141. § *b*. and § *d*.) less than a quadrant; and with c makes extremes conjunct, whose tangents (§ 157. § *s*. and § 158. § *b*.) are equal to sine A^{co}, *i. e.*, tang. b^{co} tang. c = sine A^{co}; and by transposition, tang. b^{co} = $\frac{\text{sine A}^{co}}{\text{tang. } c}$.

c = 35° 15′ 7″ tang. (ar. co.) = 0.150715 = cot. (§ 98. § *n*. 3)
Sine A^{co}, or cos. A 74° 47′ = 9.419080

Tang. b^{co}, or cot. b = 9.569795 = 69° 37′ 37″.

§ *b*. 2d. To find the value of the angle C. This is the converse of § *b*., Case 4, (§ 173.,); and therefore sine C^{co} = cos. A^{co} × cos. c.

Cos. A^{co}, or sine A = 74° 47′ = 9.984500
c = 35° 15′ 7″ cos. = 9.912022

Sine C^{co}, or cos. C = 9.896522 = 38° 00′ 7″.

§ *c*. 3d. To find the other leg a. The calculation for this is the converse of § *c*., Case 3, (§ 172.,) wherefore tang. a tang. A^{co} = sine c, and by transposition, tang. a = $\frac{\text{sine } c}{\text{tang. A}^{co}}$.

Tang. A^{co}, or cot. A = 74° 47′ (ar. co.) = 0.565421 = tang. (§ 101. § *b*.)
c = 35° 15′ 7″ sine = 9.761305

Tang. a. = 10.326726 = 64° 46′ (§ 141. § *d*.)

Digitized by Google

§ 176. The rules which have been given for the solution of any problem that can occur in right angled spherical trigonometry, are good in theory; but instances may occur in practice, wherein they will not yield the most accurate result. This apparent defect arises from the trigonometric functions by which certain arcs, or angles, that enter into calculation, are denominated. For instance: If the required part be a very small arc or angle, and the result give its log. co-sine, the solution is not a good one; because a small error in the log. cos. will produce a much larger one in the arc or angle. This arises from the difference in ratio by which an arc and its sine increase.

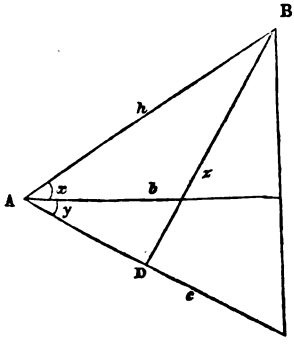
§ *a*. By referring to a logarithmic table, even of six digits in the mantissæ, it will be observed that an arc of 89° 51′ may increase 18′, or to 90° 9′, and that the value of its sine will only vary .000001.

§ *b*. The same thing is true of the co-sine of the complement of such an arc.

§ *c*. For these reasons, *the sine of an arc near* 90°, *or the cos. of one near* 1′, *should not be used in trigonometrical calculation.*

§ *d*. The value of sine and co-sine of such arcs, may be substituted, as already stated (§ 98. § *l*.), by their trigonometrical equivalents.

§ 177. Before entering upon oblique spherical trigonometry, it is necessary to prepare the student by investigating a few formulæ which look to the solution of those problems; more particularly, wherein the given parts are the three sides or the three angles, or the two sides and their contained angle, and the reverse. These formulæ are derived from the principles laid down by Props. XIX., IX. and XI. (§ 43. § 73. and § 75. etc.) Be it recollected that the sum and difference of any two quantities, determine the quantities themselves.



§ 178. To find the sine or cos. of the sum of any two angles.

§ *a*. Let B A C = *x*, and C A H = *y*, be the angles proposed. Call the line A B, *h*; and from B, draw B C = *a*, perpendicular to A C = *b*. Produce *a* to H; call C H, *s*; A H, *c*; and from B, let fall the perpendicular *z* upon *c*.

§ *b*. The two right triangles B D H, and A C H, have the angle H common; they are therefore (§ 32. § *e*.) similar (§ 23. § *b*.) Hence (§ 73.) *c* : H B, (or *a* + *s*) : : *b* : *z*, or $\frac{c}{a+s} = \frac{b}{z}$. By transposition, $z = \frac{a\,b + s\,b}{c}$

§ *c*. Now, (§ 98. § *d*.) sin. A (= *x* + *y*) = $\frac{z}{h}$; sin. *x* = $\frac{a}{h}$; and sin.

Digitized by Google

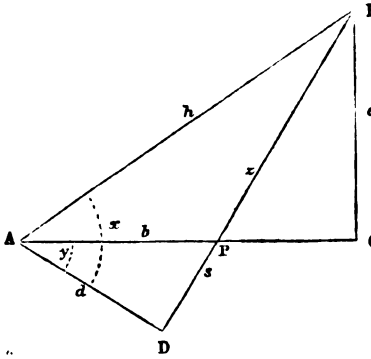
$y = \frac{s}{c}$. Adding together these last two equations, we have sin. $(x + y) = \frac{a}{h} + \frac{s}{c}$.

§ *d*. But (§ *b*.) $z = \frac{a\,b + s\,b}{c}$, therefore $\frac{z}{h} = \frac{a\,b + s\,b}{h\,c}$ = sine $(x + y)$.

§ *e*. The expression $\frac{a\,b + s\,b}{h\,c}$, is but another mode of expressing the quantities $\frac{a}{h} \times \frac{b}{c} + \frac{s}{c} \times \frac{b}{h}$. Now sine $x = \frac{a}{h}$; and sine H (§ 32. § *d*.) = cos. $y = \frac{b}{c}$; cos. $x = \frac{b}{h}$; and sine $y = \frac{s}{c}$.

§ *f*. Wherefore sine $(x + y)$ = sine x cos. y + cos. x sine y.

§ *g*. By a similar train of reasoning it may be proved, that cos. $(x + y)$ = cos. x cos. y — sine x sine y.



§ 178. To find the sine or co-sine of the difference between any two angles.

§ *a*. Let B A D = x, and C A D = y be the proposed angles; B A C is their difference. From B draw B C perpendicular to A C, and B D perpendicular to A D. Let B D = z; A P = b; and $z - s$ = B P. Now the right angled triangles A D P, and B C P, are similar, the angles at P being vertical and opposite.

§ *b*. Then (§ 73.) $a : d :: z - s : b$, or (§ XLV.) $a \div d = z - s \div b$; by transposition $a = \frac{z\,d - s\,d}{b}$.

§ *c*. Now $\frac{a}{h}$ (§ 98. § *d*.) = sine B A C = sine $(x - y)$ by (§ *a*.) construction. Taking the value of a (§ *b*.) for the second member of the equation, and dividing both members by h, we have $\frac{a}{h} = \frac{z\,d - s\,d}{h\,b}$ or $\frac{z}{h} \times \frac{d}{b} - \frac{s}{b} \times \frac{d}{h}$.

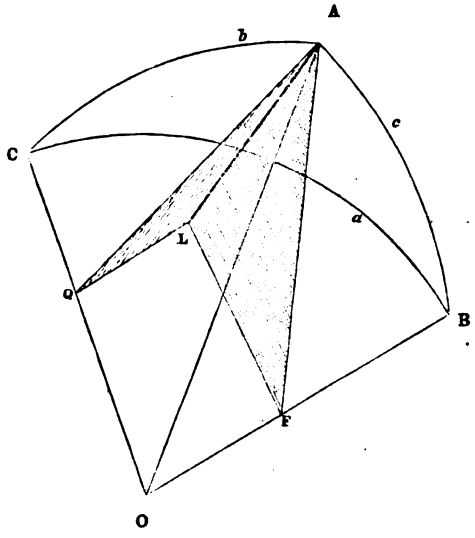
§ *d*. $\frac{z}{h}$ = sine x; $\frac{d}{b}$ = cos. y; $\frac{s}{b}$ = sine y; and $\frac{d}{h}$ = cos. x.

§ *e*. Wherefore (§ *c*. and § *d*.) sine $(x - y)$ (§ *c*.) = sine x cos. y — sine y cos. x.

§ *f*. And in the same way it may be proved cos. $(x - y)$ = cos. x cos. y + sine x sine y.

Digitized by Google

§ 179. **The sines of the opposite sides and angles of a spherical triangle are proportional.**



Let A C B, be a solid oblique angled spherical triangle, cut out from the sphere by the planes of the sides *a*, *b*, and *c*, which (§ 122.) meet at its centre O. Suppose the solid section of a sphere to rest upon the plane of the side *a*; and that O C, O A and O B, represent the edges of these planes, or the lines in which they meet.

§ *a*. From A, let fall upon O C, the perpendicular A Q. Along this line, and at right angles to the plane of *a*, insert the plane A Q L. Then (§ 122. § *a*.) Q L is also perpendicular to the edge C O, which is common to the planes of *b* and *a*, and L Q O is a right angle.

§ *b*. The angle A Q L is therefore (§ 133. § *b*.) equal to the spherical angle C; for A Q L is the angle which the planes of the spherical sides *a* and *b* make with each other.

§ *c*. Also from A, draw on the plane of *c*, the line A F perpendicular to the edge O B; and along this line A F insert a plane A F L perpendicular also to the plane of *a*.

§ *d*. Then (§ 133. § *b*.) the angle A F L is the measure of the spherical angle B, which the arcs *a* and *c* make with each other.

§ *e*. The planes A Q L and A F L are each, by construction (§ *a*. and § *c*.), perpendicular to the plane of *a*, and (§ 122. § *a*.) the line A L of their intersection is therefore necessarily perpendicular to the plane of *a*. Wherefore the two inserted triangular planes are right angled at A L Q and A L F.

§ *f*. Now in the right angled triangle (§ *e*.) O F A, we have, (§ 98. § *d*.,) sine A O F, or sine $c = \frac{A\,F}{A\,O}$.

§ *g*. Also in the right angled triangle (§ *e*.) F L A, we have, by the same rule, sine A F L, or (§ *d*.) sine $B = \frac{A\,L}{A\,F}$.

§ *h*. Now multiplying together the two equations of § *f*. and § *g*. we have:

Sine B sine $c = \frac{A\,L}{A\,F} \times \frac{A\,F}{A\,O} = \frac{A\,L}{A\,O}$.

Digitized by Google

§ *i*. Whence, by transposition sine B sine $c \times A O = A L$.

§ *j*. By a like process, we obtain from a similar investigation of the triangle O Q A, sine Q O A, or sine $b = \frac{A Q}{A O}$; and from the triangle Q L A, the equation, sine A Q L, or (§ *b*.) sine $C = \frac{A L}{A Q}$.

§ *k*. Multiplying these two equations together, we have sine C sine $b = \frac{A L}{\cancel{A Q}} \times \frac{\cancel{A Q}}{A O} = \frac{A L}{A O}$.

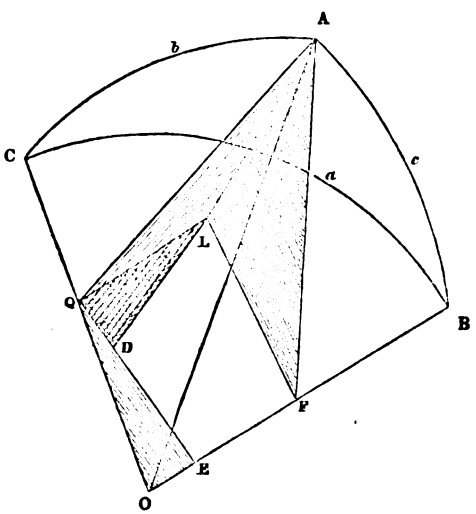
§ *l*. Wherefore, by transposition, sine C sine $b \times A O = A L$.

§ *m*. And therefore (§ *i*.) we obtain sine B sine $c \times \cancel{A O} =$ sine C sine $b \times \cancel{A O}$; which, by elimination, becomes sine B sine $c =$ sine C sine b; and by transposition, sine B $\div$ sine $b =$ sine C $\div$ sine c.

§ *n*. Hence the rule: the sines of the opposite sides and angles of a spherical triangle are proportional.

§ 180. The cos. of any side of a spherical triangle, equals the rectangle under the co-sines of the other two sides plus that under their sines into the co-sine of their included angle, *i. e.*, in the diagram annexed:

Cos. $c =$ cos. a cos. $b +$ sin. a sin. b cos. C.



§ *a*. Construct the diagram as at § 179.; then from Q, draw Q E perpendicular to O B; and from L, draw L D parallel to O B.

§ *b*. Then (§ 179. § *a*.) L Q O, being a right angle, made up of the two angles L Q D and D Q O, L Q D is the complement of D Q O. And in the right angled triangle Q E O, Q O E is also the complement of E Q O; wherefore L Q D = Q O E. But, Q O E, or, which is the same, C O B (§ 141. § *e*.) = arc *a*. Therefore,

§ *c*. L Q D = *a*.

§ *d*. In the right angled triangle O F A, with O A as Rad., we have (§ 98. § *d*.), cos. $c = \frac{O F}{O A}$, which by transposition becomes cos. $c \times$ O A = O F.

§ *e*. Now by construction, E D L F is a parallelogram, and (§ 19.) L D = E F; wherefore O E + L D = O F. Substituting this equivalent for O F in the last equation, we have,

Digitized by Google

§ *f*. O E + L D = cos. *c* × O A.

In the right angled triangle O E Q with Q O E = *a*, and with O Q as rad., we have (§ 98. § *d*.) cos. $a = \frac{O E}{O Q}$, which also by transposition, becomes

§ *g*. Cos. *a* × O Q = O E.

Then, in the right angled triangle (§ 179. § *a*.) O Q A, with A O Q = *b*, we have cos. $b = \frac{O Q}{O A}$; which, by transposition, gives the value of O Q, viz:

§ *h*. O Q = O A cos. *b*.

In the right angled triangle Q D L, with (§ *c*.) L Q D = *a*, we have sine $a = \frac{L D}{Q L}$, and by transposition,

§ *i*. Sine *a* × Q L = L D.

In the right angled triangles O Q A and Q L A, with Q O A = *b*, and A Q L = C, we have already (§ 179. § *j*.)

§ *j*. A Q = O A sine *b*; and

§ *k*. Q L = A Q cos. C.

Now multiplying equations (§ *g*. and § *h*.) together, we have O E × ~~O Q~~ = ~~O Q~~ cos. *a* × O A cos. *b*. Eliminating O Q, we have

§ *l*. O E = cos. *a* × O A cos. *b*.

Multiplying § *j*. and § *k*. together, we have ~~A Q~~ × Q L = O A sine *b* × ~~A Q~~ cos. C, which, by elimination, gives

§ *m*. Q L = O A sine *b* cos. C.

Now substituting this value (§ *m*.) of Q L, for Q L in § *i*, we have:

§ *n*. L D = O A sine *b* cos. C sine *a*.

Then, if for O E + L D, in § *f*., we substitute their values as evolved in § *l*. and § *n*., we shall have : cos. *a* × O A cos. *b* + O A sine *b* sine *a* cos. C = O A cos. *c*. But O A (§ 98.) is rad. = 1. Wherefore—

§ *o*. Cos *c* = cos. *a* cos. *b* + sine *b* sine *a* cos. C.

§ *p*. In the same way it is proved, that cos. *b* = cos. *a* cos. *c* + sine *a* sine *c* cos. B.

§ *q*. Also, cos. *a* = cos. *b*, cos. *c* + sine *b* sine *c* cos. A.

Q. E. D.

§ *r*. Each of these formulæ involves the three sides and one of the angles of a spherical triangle; consequently, when adapted to log. calculation, they lead to the determination of the angles from the sides. Indeed such is the scope of these three equations, that they afford the ground-work of formulæ for the solution of all cases in spherical trigonometry.

§ 181. To investigate formulæ, suited to log. calculation, for the angles when the sides of a spherical triangle are given.

§ *a*. Again recurring to equation § *o*., (§ 180.) we obtain by transposition, cos. $C = \frac{\text{cos. } c - \text{cos. } a \text{ cos. } b}{\text{sin. } a \text{ sin. } b}$. Now, (§ 106. § *n*.) cos. C = 2 cos.^{2} ½ C; also, (§ 105. § *g*. and § 177. § *f*.) sin. *b* sin. *a* — cos.

Digitized by Google

$b \cos. a = -\cos. (b + a)$: hence $2 \cos.^2 \frac{1}{2} C = \frac{(\cos. c - \cos. a + b)}{\sin. a \sin. b}$

$= 2 \sin. \frac{1}{2} \frac{(a + b + c) \sin. \frac{1}{2} (a + b - c)}{\sin. a \sin. b}$.

The 2 and 2 in each member of the equation, cancel; wherefore we have:

§ *b*. $\text{Cos. } \frac{1}{2} C = \sqrt{\sin. \frac{1}{2} \frac{(a + b + c) \sin. \frac{1}{2} (a + b - c)}{\sin. a \sin. b}}$.

§ *c*. In the same way it may be proved, calling $s = (a + b + c)$,

$\text{Cos. } \frac{1}{2} B = \sqrt{\frac{\text{sine } \frac{1}{2} (s) \text{ sine } \frac{1}{2} (s) - b}{\text{sine } a, \text{ sine } c}}$. And,

$\text{Cos. } \frac{1}{2} A = \sqrt{\frac{\text{sine } \frac{1}{2} (s) \text{ sine } \frac{1}{2} (s) - a}{\text{sine } b, \text{ sine } c}}$.

§ *d*. By a similar process the equivalent for tang. $\frac{1}{2}$ the required angle may be obtained. But as the formulæ just deduced are as convenient in practice as any others, and are generally preferred to all others, they are considered quite sufficient. It is the object of this work to explain only so much of theory as is required to make a PRACTICAL NAVIGATOR of the student; for any further investigation, therefore, of formulæ for the angles from the sides, he is referred to works exclusively devoted to spherics.

§ 182. To investigate formulæ for the sides, when the three angles are given.

§ *a*. If in any spherical triangle, the angles be A, B, C, and the sides *a*, *b*, *c*, then (§ 133. § *e*.) 180° — A, 180° — B, 180° — C, will be the sides of its polar triangle; and 180° — *a*, 180° — *b*, 180° — *c*, the angles. Wherefore, when the three angles of a triangle are given, we have but to consider the proposed triangle as a polar triangle, whose angles are supplemental to the sides of the given triangle. Therefore, the formulæ which have already been investigated for the angles where the sides are given, have but to be applied to the supplemental triangle where three angles are given, and we have the formulæ required. Adapting, therefore, the expressions, § *o*., § *p*. and § *q*. (§ 180.), to the polar triangle, we obtain the equations.

§ *b*. $\text{Cos. } c = \frac{\text{cos. C} + \text{cos. B cos. A}}{\text{sine B sine A.}}$.

§ *c*. $\text{Cos. } b = \frac{\text{cos. B} + \text{cos. A cos. C}}{\text{sine A sine B}}$.

§ *d*. $\text{Cos. } a = \frac{\text{cos. A} + \text{cos. B cos. C}}{\text{sine B sine C}}$.

From which, by a process similar to that just performed (§ 181. § *b*.) with regard to the sides of its supplemental triangle, we obtain the expressions:

§ *e*. $\text{Cos. } \frac{1}{2} c = \sqrt{\cos. \frac{1}{2} \frac{(C + B + A) - A \cos. \frac{1}{2} (C + B + A) - B}{\sin. A \sin. B}}$.

§ *f*. $\text{Cos. } \frac{1}{2} b = \sqrt{\cos. \frac{1}{2} \frac{(B + A + C) - C \cos. \frac{1}{2} (B + A + C) - A}{\sin. A \sin. C}}$.

Digitized by Google

§ *g*. Cos. $\frac{1}{2}a = \sqrt{\cos.\frac{1}{2}\frac{(A+B+C)-C\cos.\frac{1}{2}(A+B+C)-B}{\sin. B \sin. C}}$.

§ 183. To investigate a formula for an opposite part, when two sides and their contained angle, or a side and its adjacent angles, are given.

§ *a*. If the value of cos. *b*, in § *p* (§ 180.) be substituted for cos. *b* in § *q*, (§ 180.) we shall have the value of cos. *a* = cos. *a* cos. *c* + sin. *a* sin. *c* cos. B cos. *c* + sin. *b* sin. *c* cos. A. Or, cos. *a* = cos. *a* cos.^{2} *c* sin. *a* sin. *c* cos. B + sin. *b* sin. *c* cos. A. Now, (§ 105. § *c*.) cos.^{2} *c* = R^2 — sin.^{2} *c*—and (§ 98.) R^2 = 1.

§ *b*. Wherefore, substituting this equivalent for cos.^{2} *c*, and dividing by the common factor sin. *c*, we have, cos. *a* sin. *c* = sin. *a* cos. *c* cos. B + sin. *b* cos. A. Now, (§ 179. § *m*.) the value sin. $b = \frac{\sin. B \sin. a}{\sin. A}$; and substituting this value for sin. *b* in the last equation (§ *b*.), we obtain:

§ *c*. Cos. *a* sin. *c* = sin. *a* cos. *c* cos. B + $\frac{\sin. B \cos. A \sin. a}{\sin. A}$.

Dividing by sin. *a*, we have:

§ *d*. $\frac{\text{Cos. } a \sin. c}{\sin. a} = \cos. c \cos. B + \frac{\sin. B \cos. A \sin. a}{\sin. A}$.

§ *e*. But (§ 98. § *m*.) $\frac{\cos.}{\sin.} = \cot.$ Wherefore,

§ *f*. Cot. *a* sin. *c* = cos. *c* cos. B + sin. B cot. A.

§ *g*. Hence, the rectangle under the cot. of one side and sine of another, is equal to the rectangle under co-sine of the latter side and cos. of the contained angle, plus the sine of this angle into the cot. of the angle opposite the first side.

§ *h*. By means of four other proportions called "Napier's Analogies," that celebrated mathematician has established four formulæ that serve greatly to simplify some of the cases which we have been considering.

NAPIER'S ANALOGIES.

§ 183. Referring again to the equations § *o*., § *p*., § *q*. under § 180., —if we eliminate cos. *c* from § *o*. and § *q*., and reduce the remainder, we shall have

§ *a*. Cos. A sine *c* = cos. *a* sine *b* — cos. C sine *a* cos. *b*.

§ *b*. After the same manner, we derive from § *o*. and § *p*., that cos. B sine *c* = cos. *b* sine *a* — cos. C sine *b* cos. *a*.

First adding these two equations, and then reducing, we obtain

§ *c*. Sine *c* (cos. A + cos. B) = (— cos. C) sine (*a* + *b*).

But (§ 179. § *l*.) $\frac{\text{sine } c}{\text{sine C}} = \frac{\text{sine } b}{\text{sine B}} = \frac{\text{sine } a}{\text{sine A}}$. Wherefore—

§ *d*. Sine *c* (sine A + sine B) = sine C (sine *a* + sine *b*), also

§ *e*. Sine *c* (sine A — sine B) = sine *c* (sine *a* — sine *b*).

Dividing § *d* by § *c*, sine *c* is cancelled, and we have—

§ *f*. $\frac{\text{Sine A + sine B}}{\text{Cos. A + cos. B}} = \frac{\text{sine C}}{-\cos. C} \cdot \frac{\text{sine } a + \text{sine } b}{\text{sine } (a+b)}$.

Digitized by Google

Dividing § *e.* by the same, we have, in like manner,

§ *g.* $\frac{\text{Sine A} - \text{sine B}}{\text{Cos. A} + \text{cos. B}} = \frac{\text{sine C}}{-\text{cos. C}} \frac{\text{sine } a - \text{sine } b}{\text{sine } (a + b)}$.

§ *h.* Now (§ 98. § *m.*) $\frac{\text{sine}}{\text{cos.}} = \text{tang.}$; wherefore (§ 78. § *h.*) tang. $\frac{1}{2}$ (A + B) = cot. $\frac{1}{2}$ C $\frac{\text{cos. } \frac{1}{2} (a - b)}{\text{cos. } \frac{1}{2} (a + b)}$.

§ *i.* Tang. $\frac{1}{2}$ (A — B) = cot. $\frac{1}{2}$ C $\frac{\text{sine } \frac{1}{2} (a - b)}{\text{sine } \frac{1}{2} (a + b)}$.

Which two formulæ are used for determining the two angles from the two sides and their contained angle.

§ *j.* By applying these two analogies to the polar triangle, and recollecting (§ 182. § *a.*) its supplemental relations, we obtain from them two other analogies, for determining the two sides when one side and its adjacent angles are given. These two are,

§ *k.* Tang. $\frac{1}{2}$ (a + b) = tang. $\frac{1}{2}$ c $\frac{\text{cos. } \frac{1}{2} (\text{A} - \text{B})}{\text{cos. } \frac{1}{2} (\text{A} + \text{B})}$.

§ *l.* Tang. $\frac{1}{2}$ (a — b) = tang. $\frac{1}{2}$ c $\frac{\text{sine } \frac{1}{2} (\text{A} - \text{B})}{\text{sine } \frac{1}{2} (\text{A} + \text{B})}$.

OBLIQUE SPHERICS.

§ 192. In every oblique spherical triangle, there are *six parts*, any three of which constitute sufficient data (§ 145.) for determining the value of any of the remaining parts by means of trigonometrical calculation.

§ *a*. Every problem in oblique spherical trigonometry is included in one of the six following cases; in which the data are,

1st. Two sides and angle opposite to one of them.

2d. Two angles and the side subtending either.

3d. Two angles and the side between them.

4th. Two sides and the angle they include.

5th. The three sides.

6th. The three angles.

§ *b*. When any one of the first four cases, comprises the data of the problem, it may be solved by right angled trigonometrical operations; for this purpose the proposed triangle (§ 147. § *a*.) must be divided into two right angled triangles, by drawing a perpendicular from one of the angles upon its opposite side.

§ *c*. The perpendicular must be so drawn, that *two* of the given parts must be on the *same side* of it, and consequently, in one of the right angled triangles, into which the triangle of the problem is divided.

§ *d*. The rules in right angled trigonometry, for determining *in species* an unknown side or angle, (*i. e.*, whether it be greater or less than 90°), do not hold good in all cases in oblique trigonometry: for—

§ *e*. The opposite sides and angles of oblique spherical triangles, are not necessarily of the same affection.

§ *f*. But if the greatest *side* be greater than a quadrant, it and its opposite angle are of the same affection.

§ *g*. The converse of this does not hold good; for the sides (§ 136. § *a*.) of a spherical triangle may be indefinitely small, and the sum of the angles (§ 137.) being greater than two right angles, an obtuse angled spherical triangle may be formed of these indefinitely small sides; in which case an obtuse angle and its subtending side will be unlike.

§ *h*. In most cases though, there are circumstances connected either with the condition of the problem, or of the triangle it involves, by which the species of the part required may be determined. Some of these circumstances are mentioned on the next page.

Digitized by Google

§ *i*. If an angle of a triangle be greater than 90°, an arc drawn from it, perpendicular to the subtending side, will fall *within* such triangle.

§ *j*. If the angles adjacent to the base, be of the same affection, the perpendicular falls upon it, also within the triangle.

§ *k*. If all the angles of a triangle be not of the same affection, and a perpendicular arc be drawn from one of the angles which is less than 90° upon the subtending side, it will fall *without* the triangle.

§ *l*. An opposite side and angle of a spherical triangle cannot be unlike, unless the sine of this side be greater than the sines of the other sides.

§ *m*. The sine of the angle opposite to such a side is also greater than the sines of the two other angles.

§ *n*. In an isosceles triangle, each side and its opposite angle are alike.

§ *o*. If an obtuse side be opposite to an acute angle in any triangle, the two other sides are unlike; and (§ 191.) they and their opposite angles are of the same affection; consequently, the two angles are unlike.

§ *p*. If an obtuse angle subtend an acute side, the other sides and angles are all alike.

§ 193. Whether the perpendicular fall within or without the triangle, the less segment of the base is next to that angle which, of the two adjacent to the base, is the nearer 90°.

§ *a*. When the perpendicular falls within the triangle, the angles which it makes at the vertex are together equal to the vertical angle, and the segments of the base are together equal to the base.

§ *b*. But when the perpendicular falls without the triangle, the difference of the angles which it makes at the vertex is equal to the vertical angle, and the base is equal to the difference of the segments of the base.

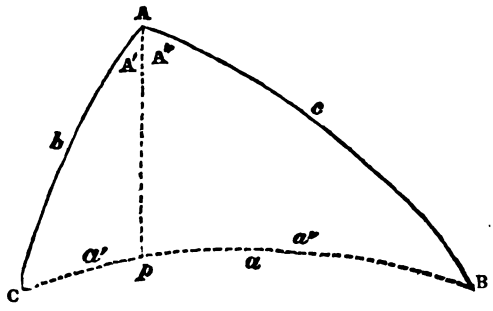
§ 194. If a side and its subtending angle be each less than 90°, a smaller side and its opposite angle, of the same triangle, must be (§ 139.) of the same affection.

§ 195. If the sum of two angles of a triangle be less than 90°, the third angle (§ 137.) is greater than a right angle.

§ 196. By writing co-tang. for the arithmetical complement (§ 101. § *b*.) of the tangent; sec. for the arithmetical complement of cos.; co-sec. for the arithmetical complement of sine, etc., greater simplicity and uniformity of calculation will be effected.

Digitized by Google

CASE I.



§ 197. Given two sides (b and c) and an angle (C) opposite to one of them,

$b = 21° 17'$
$c = 74° 14'$
C $= 69° 10'$

To find the other parts.

§ *a*. If the third side a, or its opposite angle A, be computed, the other two parts may be determined (§ 179. § *n*.) by the proportion between the sines of opposite side and angles. B is also determinable by the same rule, viz: Sin. B $= \frac{\text{sine } b \text{ sine C}}{\text{sine } c}$, or (§ 196.) $=$ sine b sine C co-sec. c.

Thus,
$c = 74° 14'$ co-sec. $= 0.016655$
C $= 69° 10'$ sin. $= 9.970635$
$b = 21° 17'$ sin. $= 9.559883$

Sin. B, $20° 38' 27'' = 9.547173$

§ *b*. But suppose the required part should be a, or its opposite angle A; the rule of sines of opposite sides and angles would not apply. It is necessary therefore to investigate a formula for finding either of these two parts directly from the data.

By the right angular process (§ 192. § *b*.)

§ *c*. From A let fall the perpendicular A p so as to divide the proposed triangle (§ 192. § *c*.) into two right angled triangles, one of which, as A p C, shall contain (b and C) two of the given parts. Let C p and B p, the distance of C and B from the perpendicular A p, be called auxiliary arcs a' and a''.

§ *d*. With b and C given, to find auxiliary a', we have the rule of tangents conjunct (§ 158. § *c*.): cos. C $\div$ cot. b $=$ tang. a', *i. e.*:

$b = 21° 17'$ (§ 196.) tang. $= 9.590562$
C $= 69° 10'$ cos. $= 9.551024$

Aux. a' $7° 53' 16''$ tang. $= 9.141586$

} To find a' and a''.

§ *e*. Cos. A $p = \frac{\text{cos. } b}{\text{cos. } a'}$. Also in the other triangle, cos. A p $= \frac{\text{cos. } c}{\text{cos. } a''}$. Wherefore, $\frac{\text{cos. } b}{\text{cos. } a'} = \frac{\text{cos. } c}{\text{cos. } a''}$. Hence cos. $a'' = \frac{\text{cos. } c \text{ cos. } a'}{\text{cos. } b}$ = sec. b (ar. co.)

Digitized by Google

Two sides and an opposite angle.

C = 74° 14′ cos.	=	9.434122
a' = 7° 52′ 16″ cos.	=	9.995890
b = 21° 17′ sec.	=	0.030679
Aux. a'' 73° 12′ 38″ cos.	=	9.460691

To find a. § *f.* C and B (§ 194.) are less than 90°, therefore (§ 141. § *b.*) A *p* and a' are each less than 90°; and the perpendicular A *p* (§ 189. § *a.*) falls within the triangle, making the sum of the segments a' and a'' = *a*—(§ *d.* and § *l.*) Therefore 7° 53′ 16″ + 73° 12′ 38″ = *a* of 81° 5′ 54″.

§ *g.* The angle A may also be determined directly from the data by the intervention of the Catholic Proposition. Thus: with C and *b* for data, A'^{co} and C^{co} are extremes conjunct; therefore cos. *b* tang. C = cot. A′ (§ 171. § *a.*)

§ *h.* With *b*, A′ and A *p* as circular parts, we have, by the rule of tangents conjunct, tang. A $p = \frac{\text{cos. A}'}{\text{cot. } b}$; with *c*, A″ and A *p* as circular parts, the same rule gives another equivalent for A *p*, viz: tang. A $p = \frac{\text{cos. A}''}{\text{cot. } c}$. Wherefore $\frac{\text{cos. A}'}{\text{cot. } b} = \frac{\text{cos. A}''}{\text{cot. } c}$, and by transposition cos. A″ = cot. *c* cos. A′ tang. *b*, (§ 196.)

§ *i.* $A' + A'' \underset{\infty}{=} A$, according as the perpendicular A *p* falls within or without the triangle. Whence (§ *g.* and § *h.*) the general rule for finding the contained angle where two sides and the angle opposite to one of them are given:

Rule. § *j.* Tang. of the given angle into cos. of its adjacent side equals cot. auxiliary A′.

§ *k.* The rectangle under tang. of the same side and cotang. of the other given side into cos. auxiliary A′ equals cos. of the other auxiliary angle A″. And (§ 193. § *a.* and § *b.*) the sum or difference of these auxiliary angles equals the required angle.

Calculation by (§ *g.* and § *h.*)

(§ *g.*) c = 74° 14′ cot. = 9.450777 (§ *h.*)

b 21° 17′ cos. = 9.969321 - - - tang. = 9.590562

C 69° 10′ tang. = 0.419611

Cot. A′ = 0.388932 = 22° 12′ 51″ cos. = 9.966506

Cos. A″ = 84.9.21 = 9.007845

A = 106° 22′ 12″ (§ *i.*)

The formula for this calculation is arranged in the most convenient manner. The value of auxiliary A′ is evolved during the process of finding that of A″. The log. tang. and cos. *b*, are taken out at one opening of the tables; so also is the value of A′ and its cos. Method and arrangement in calculation should by no means be neglected. They

Digitized by Google

promote accuracy and facilitate computation. It is therefore the business of every calculator to introduce system in his operations. It makes verification more easy.

§ *l.* To find the value of the third side *a*, with the help of auxiliaries derived directly from the data. Let the two segments *a'* and *a''* be the auxiliaries.

§ *m.* With *a'*, C and *b* for the problem, *a'* and b^{cs} are conjunct extremes; and their tangents = sine C^{cs} according to Napier's Rule. Wherefore, availing ourselves of the artifice so often resorted to (§ 98. § *r.*), by which (§ 101.) subtraction is converted into addition, we have tang. *a'* = cos. C *tang. b.*

§ *n.* Also, with *b* for middle part, *a'* and A *p* for extremes disjunct, we have cos. A $p = \frac{\text{cos. } b}{\text{cos. } a'}$; and, with like parts in the other triangle, we have cos. A $p = \frac{\text{cos. } c}{\text{cos. } a''}$. Wherefore $\frac{\text{cos. } b}{\text{cos. } a'} = \frac{\text{cos. } c}{\text{cos. } a''}$. The unknown part here is *a''*. Wherefore, by transposition, and § 98. § *r.*,

Cos. *a''* = cos. *c* cos. *a' sec. b.* Whence the rule—

Rule.

§ *o.* Cos. of the given angle into the tang. of its adjacent side, equals tang. of auxiliary *a'*, (§ *m.*).

§ *p.* And the arcs of the same side into the rectangle under the sec. of the other side, and co-sine of this auxiliary equals cos. of auxiliary *a''*. And (§ 193. § *a.* and § *b.*) $a' + a'' = a$.

§ *q.* If the two angles adjacent to the base be each less than 90°, the perpendicular falls within the triangle. But if these two angles be unlike, the perpendicular falls without the triangle, and then the *difference* of the auxiliaries is the required part.

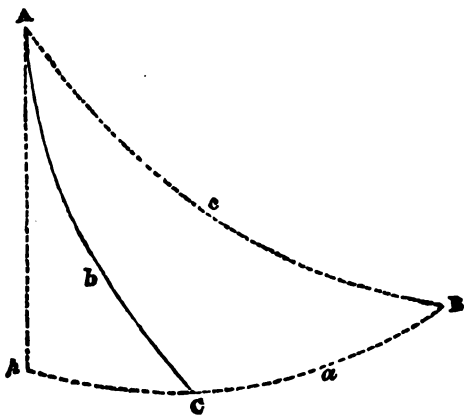
To calculate the auxiliaries by § *m.* and § *n.*

§ *r.*		*c* 47° 14′ cos. = 9.434122	
b 21° 17′ tang. = 9.590562		- - sec. 0.030679	
C 69.10 cos. = 9.551034			
tang. *a'* = 9.141586	= 7° 53′ 16″ cos. = 9.995872		*Two sides and an opposite angle.*
	cos. *a''* 73° 12′ 39 = 9.460673		
	a = 81° 5′ 55″		

Other formulæ for the two problems in which the unknown side *a* and its opposite angle A are concerned, may be established for finding either. The student can establish them. It is not deemed necessary to investigate them here, as this work does not pretend to give more than is necessary to a complete knowledge of the mathematical principles of navigation, and in *practical* navigation a problem seldom or never occurs wherein the sides and an opposite angle are the *only* given parts of a spherical triangle.

Digitized by Google

CASE II.



In which two angles and an opposite side are given.

§ 198. Given B, C, and the side b, opposite to B.

$B = 29° 16'$
$C = 150° 51' 50''$
$b = 74° 46'$

To find A, c and a.

§ a. The value of c is found by means of the proposition (§ 179. § m.) established between the sines of opposite sides and angles; sin. c : sin. C : : sin. b : sin. B; which by transposition and the substitution (§ 108. § e.) of the reciprocal of *sin.* B, (§ 98. § n. 2, and § 98. § r.) becomes,

Sin. C sin. b *co-sec.* B = sin. c.

B = 29° 16′ co-sec.	=	0.310802
b = 74° 46′ sin.	=	9.984466
C = 150° 51′ 50″ sin.	=	9.687427
Sin. c = 9.982695 = 106° 4′ 2″		

§ b. But suppose either of the other two parts A or a, be required; neither of them can be determined from the ratio between the sines of opposite sides and angles. But either of them may be determined by means of a perpendicular drawn in such a manner (§ 192. § c.), that two of the given parts may be common to the same triangle. Suppose the perpendicular thus drawn to fall without the triangle (as it will, unless B and C be of the same affection), as A p upon a produced. Then, in the triangle A p C, the two given parts are b, and (§ 132.) the supplement of C = 29° 8′ 10″.

To determine the two segments (§ 79. § e.) p C and p B of the base a, and thence the value of a.

To find p C *and* B p.

§ c. In the right angled triangle A p C with b and A C p given, using (§ 88. § c.) the reciprocal (§ 98. § r.) of *cot.* b, we have (§ 158. § b.) tang. C p = cos. C *tang.* b.

§ d. In the triangle A p C, A p and A C p are conjunct extremes to C p. Therefore, by Napier's rules—and transposition, tang. A $p = \frac{\text{sine C } p}{\text{cot. A C } p}$.

§ e. And in the triangle A p B, where A p and B^{co} are conjunct ex-

Digitized by Google

tremes to B p, we have, by the same rule, tang. A $p = \frac{\text{sine B } p}{\text{cot. B}}$, wherefore $\frac{\text{sine C } p}{\text{cot. A C } p} = \frac{\text{sine B } p}{\text{cot. B}}$. By transposition and substitution (§ 98. § *e*. § 101.) sine B p = sine C p *tang*. A C p, cot. B.

§ *f*. C p + B p = a, according as A p falls without or within the triangle, and it falls without (§ *b*.) when either of the two angles B and C is less, and the other greater, than 90°; and it falls within when both are less, or both greater, than 90°.

CALCULATION.

By § *c*.

C 150° 61′ 50″ cos. (§ *c*.) = 9.941246 tang. (§ *e*.) = 9.746181

b 74.46. tang. 0.564922

Tang. C p 72° 41′ 3″ = 0.506168 - sine = 9.979857

B 29° 16′ cot. = 0.251495

Sine B p 108° 16′ 15″ - - - - - - = 9.977533

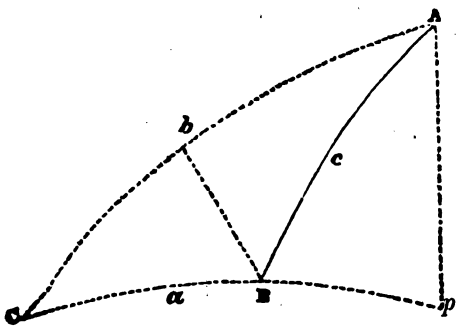
a = 35° 35′ 12″ (§ *f*.)

§ *g*. Whence the general rule for practice:

The rectangle under tang. given side and cos. its adjacent angle, is tang. auxiliary arc a' (§ *c*.); and (§ *e*.) sine of this auxiliary *multiplied* into the *product* of the tang. of the same angle by cot. the other given angle, is sine of the second auxiliary arc (§ *e*.) The sum or difference of which auxiliaries (§ *f*.) gives the required side a. *Rule.*

§ *h*. The side a being determined, its opposite angle A is found by means of the proportions between the sines of opposite sides and angles, so often referred to.

CASE III.



§ 199. In which two angles (A and B) and the side (c) between them, are given, viz:

A = 19° 41′
B = 134° 17′
c = 36° 19′

To find C, b and a.

§ *a*. The perpendicular may be drawn from either of the given angles; for in either case, the two other given parts will be on the same side of it. Suppose it

Digitized by Google

be drawn from A and fall without the given triangle, as at A p, then the given side c and the supplement A B p of the given angle B are both in the same right angled triangle A p B. Suppose the perpendicular be drawn from the other given angle B, and that it falls within the triangle, then the two given parts c and A are in the same right angled triangle A b B.

1st. To find C.

§ b. Call B A p auxiliary A'. Then in the right angled triangle A p B, A'^{co} and B^{co} are extremes conjoined to the middle part c^{co}, wherefore, by the Catholic Proposition and transposition, we have the formula cos. c *tang.* B = cot. aux'l A'.

§ c. Also, taking B^{co} for the middle part, A'^{co} and A p for extremes disjunct, we have, (Demonstration 7, § 160.) cos. A p = cos. B ÷ sin. A'.

§ d. And, in A p C, taking C A p to be the sum or difference ($\underset{S}{+}$) of A and A' according as (§ 193. § a. and § b.) the perpendicular falls within or without the given triangle, we have another equivalent of cos. A p = cos. C ÷ sin. (A $\underset{S}{+}$ A'.)

§ e. Wherefore cos. C $\underset{S}{=}$ cos. B *co-sec.* A' sin. (A $\underset{S}{+}$ A'.)

Calculation to find C.

c 36° 19′ cos. = 9.906203 (§ b.)	(§ e.)
B 134° 17′ tang. = 0.010866	cos. = 9.843984
Cot. A′ = 9.917069 = 50° 26′ 15″	co-sec. 0.112985
(A + A′) (§ a. and § 193. § a.) = 70° 7′ 15″	sine = 9.973318
C = 31° 36′ 10″	cos. = 9.930287

Rule. { § f. Whence the rule: co-sine of the given side, and tangent of either angle give co-tang. auxiliary A'. Then co-sec. auxiliary A' and cos. the same given angle, multiplied by the sine of the *sum* (§ 193. § a. and § b.) or *difference* of the other given angle and auxiliary A', give cos. of the required angle.

To find either of the two other sides, as b, with the help of auxiliaries.

§ g. With B A p as auxiliary A', it is found as at § b, viz: cos. c *tang.* B = cot. A'.

§ h. Then with A'^{co} as middle part between the conjuncts A p and c^{co}, we have, by the Catholic Proposition, sine A'^{co} or cos. A' = tang. A p cot. c.

§ i. Also in the triangle A p C, in which the angle C A p is equal to the sum or difference of the given angle A and auxiliary A' according (§ 193. § a. and § b.) as the perpendicular from A falls within or without the triangle, we have, by the same rule, cos (A $\underset{S}{+}$ A') = tang. A p cot. b.

Digitized by Google

§ *j*. Dividing these two equations by each other, we have,

$$\frac{\cos.\ (A + A')}{\cos.\ A'} = \frac{\text{tang. } \frac{1}{2}p \text{ cot. } b}{\text{tang. } \frac{1}{2}p \text{ cot. } c}.$$

Eliminating tang. A p, we have, $\frac{\cos.\ (A + A')}{\cos.\ A'} = \frac{\text{cot. } b}{\text{cot. } c}$; which by transposition, and by means of the artifice pointed out under § *b*., (§ 101.) shows cot. b = cos. (A + A') *sec.** A' cot. c.

To find b, by calculation.

B 134° 17′ tang.	= 0.010866	(§ *g*.)
c 36° 19′ cos.	= 9.906204	- - - cot. = 0.133700
Cot. A′	= 9.917070	= 50° 26′ 15″ - sec. 0.195915
A′	= 19.41	
(A + A′)	= 70° 7′ 15″	Cos. 9.531528
		Cot. *b*, 54° 0′ 27″ = 9.861143

§ *k*. Whence the rule: Cos. given side and tang. of the angle opposite the required side, is co-tang. auxiliary A'. Then sec. auxiliary and cot. given side multiplied by the co-sine of the sum or difference (§ 193. § *a*. and § *b*.) of said auxiliary and the other given angle, is co-tang. the required side. } *Rule.*

§ *l*. A triangle that has an angle or a side greater than 180°, should never be used in the solution of trigonometric problems; therefore if the sum or difference of an arc or angle and its auxiliary, exceed 180°, the difference between it and 180°, is the proper quantity to be used.

§ *m*. The most common method for determining the two unknown angles of this case, is derived from Napier's Analogies (§ 183. § *k*. and § *l*.)

By § *k*.		(§ *l*.)
Tang. ½ *c* (18° 9′ 30″)	= 9.515844	tang. = 9.515844
Sin. ½ (A — B) = 57° 18′	= 9.925060	cos. = 9.732587
Co-sec. ½ (A + B) = 76° 59′	= 0.011305	*sec.* 0.647365
Tang. ½ (*a* — *b*)	9.452209	= 15° 48′ 58″
Tang. ½ (*a* + *b*)	- -	38° 11′ 29″ = 9.895796
The greater side *b*		= 54° 00′ 27″ (§ 77. § *g*. (& § 139.)
The less do. *a*		= 22° 22′ 31″

* In order to perform our calculations always by the *addition* of the logarithms used, we have resorted to the artifice, when a log. was to be subtracted, of taking its reciprocal (§ 98. § *r*.) as its ar. co. (§ 101.), and *italicising* it, as above.

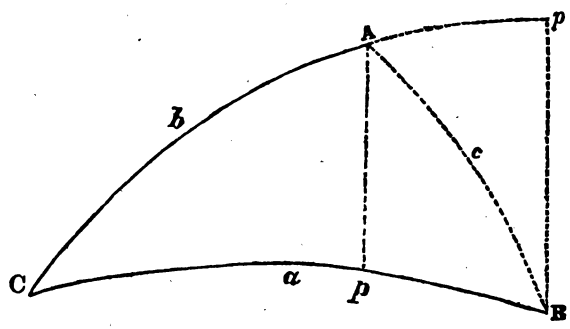
Digitized by Google

Rule. { § *n*. Whence the rule. The tangent of *half* the given side into the rectangle under the *co-sec.* of the half *sum* and sine of the half *difference* of the two given angles, gives tang. of half the difference between the two required sides.

Then the tang. of *half* the given side into the rectangle under the *sec.* of the half *sum* and cos. half *difference*, of the two given angles, is tang. half the sum of the sides required.

CASE IV.

§ 200. Given the sides a and b, and their contained angle C.



$a = 109° 30'$
$b = 60° 00'$
C $= 27° 6'$

This is the converse of Case 3, for we have given in this what it is required to find in that.

To find the other parts as A B, and c, by the Catholic Proposition: and 1st B.

§ *a*. Call either segment, as C p of the base, auxiliary arc a'.

§ *b*. Then the *difference* between a' and a, or $a \backsim a'$ will give the other segment as B p.

§ *c*. The proposed triangle is thus divided into two right angled triangles A p c and A p B.

To find auxiliary arc a' or C p with C^{co} as middle part: a' and b^{co} are extremes conjunct, wherefore (§ 158. § *c*.)

§ *d*. Tang. a' = cos. C *tang*. b, and (§ *b*.) $(a \backsim a') =$ B p.

To find the required angle B.

§ *e*. With a' and $(a \backsim a')$ as middle parts in each triangle, we have,

1st. Tang. A $p = \frac{\text{sine } a'}{\text{cot. C}}$, and 2d, tang. A $p = \frac{\text{sin. } (a \backsim a')}{\text{cot. B}}$. Wherefore, $\frac{\text{sine } (a \backsim a')}{\text{cot. B}} = \frac{\text{sine } a'}{\text{cot. C}}$. And by transposition:

§ *f*. Cot. B = sine $(a \backsim a')$ cot. C *co-sec.* a'.

Digitized by Google

To find either angle, as B, by calculation.

Tang. b 60° 0′ = 0.238561 (§ *d*.)
Cos. C 27° 6′ = 9.949494 (§ *f*.) cot. = 0.290963

Tang. aux. a' = 0.188055 = 57° 2′ 4″ co-sec. 0.076240

a = 109° 30′ 00″

($a \sim a'$) 52° 27′ 56″ sine 9.899268

Cot. B 28° 25′ 54″ = 0.266471

§ *g*. By letting the perpendicular fall from B, the angle A may be found precisely after the same manner. Whence the rule.

§ *h*. The rectangle under cos. the given angle, and tang. side opposite the required angle, is tang. auxiliary a'.

§ *i*. Then, sine the *difference* between the other given side and aux. a', into rectangle co-sec. aux. a', and cot. the given angle is cot. the required angle. } *Rule.*

To find the third side c, by means of the Catholic Proposition.

§ *j*. Let the perpendicular A p fall within the triangle as before, and the segment C p of the base be aux. a' again. Then with b^{co} and c^{co} as a middle part in each triangle, and the two legs as disjunct extremes, we have (§ 157. § *f*.)

§ *k*. Cos. A $p = \frac{\text{cos. } b}{\text{cos. } a'}$, and cos. A $p = \frac{\text{cos. } c}{\text{cos. } (a \sim a')}$. Wherefore

§ *l*. Cos. c = cos. b. *sec.* a' cos. ($a \sim a'$).

To find c by calculation.

Cos. C 27° 6′ = 9.949494 (§ *d*.)
Tang. b 60° 0′ = 0.238561 cos. = 9.698970 (§ *l*.)

Aux. a' = 57° 2′ 4″ tang. = 0.188055 sec. 0.264293

a' 109° 30′

($a \sim a'$) 52° 27′ 56″ - - - cos. 9.784786

Cos. c 55° 57′ 24″ = 9.748049

Hence the rule for finding the third side with the help of an auxiliary:

§ *m*. The rectangle under cos. the given angle and tang. of either side, is auxiliary a'.

§ *n*. Then cos. the same side into the rectangle under sec. a' and cos. the *difference* between a' and the other given side is cos. the third side. } *Rule.*

It is sometimes desirable to find A and B together. This may be done without the help of auxiliaries and by means of Napier's Analogies, (§ 183.): By § *h*. (§ 183.) we have,

§ *o*. Tang. $\frac{1}{2}$ (A + B) = cot. $\frac{1}{2}$ C cos. $\frac{1}{2}$ (a — b) *sec.* $\frac{1}{2}$ (a + b). And,

Digitized by Google

§ *p.* (§ 183. § *i.*) tang. $\frac{1}{2}$ (A — B) = cot. $\frac{1}{2}$ C sin. $\frac{1}{2}$ (a — b) *co-sec.* $\frac{1}{2}$ (a + b).

To find A and B by calculation.

(§ *o.*)				(§ *p.*)
Cot. $\frac{1}{2}$ C	13° 33′	= 0.617980	-	0.617980
Cos. $\frac{1}{2}$ (a — b)	24° 45′	9.958154	sin.	9.621861
Sec. $\frac{1}{2}$ (a + b)	84° 45′	1.038571	co-sec.	0.001826
Tang. $\frac{1}{2}$ (A + B)	88° 36′ 32″	= 1.614705		
Tang. $\frac{1}{2}$ (A — B)	60° 10′ 38″	- - - -		0.241667
(§ *p.*)	148° 47′ 10″ = A 28° 25′ 54″ = B	The $\frac{1}{2}$ sum and $\frac{1}{2}$ diff. (§ 77. § *g.*) give the angles.		

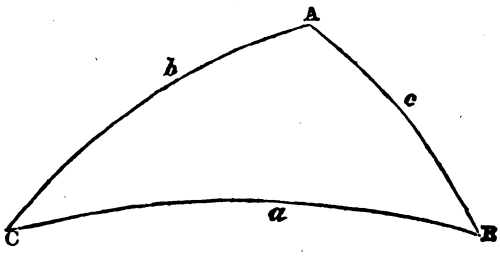
§ *q.* Hence the rule:

Rule. Cot. half the given angle into the rectangle under cos. half sum and *sec.* half difference of the two sides, is tang. half the sum of the two required angles. And

§ *r.* Cot. half the given angle into the rectangle under the sin. of half the difference and *co-sec.* half the sum of the two given sides, gives tang. half the difference of the two required angles.

CASE V.

§ 201. Where the three sides, a, b and c, are given, to find the angles.



$a = 66°$
$b = 44°$
C = 30°.

Neither in this, nor in the case which follows it, can the value of any one of the unknown parts be determined by the Catholic Proposition; for the triangle cannot be so divided (§ 192. § *c.*) into right angled triangles, that two of the given parts may be in either of them. This and Case 4 (§ 200.) are of frequent occurrence, and therefore of the more importance in practical navigation. The problem for finding azimuths, and time of day at sea, come under Case 5. This and the preceding case are both employed in finding longitude by "Lunars," and latitude by "Double Altitudes," etc. As in the other cases, so in this, there are several methods by which the required part may be found. In every instance the methods best calculated for practical purposes are given.

To find either angle as A.

§ *a.* According to § 181. § *c.*, we have

Digitized by Google

Cos. $\frac{1}{2}$ A $= \sqrt{\frac{\text{sine } \frac{1}{2}(a+b+c) \text{ sine } \frac{1}{2}(a+b+c)-a}{\text{sine } b, \text{ sine } c}}$, which, substituting for sine b sine c, (§ 101. § *b.*,) their arithmetical complements, (§ 108. § *f.* and § 98. § *i.*), gives

§ *b.* Cos. $\frac{1}{2}$ A $= \sqrt{}$ sine $\frac{1}{2}(a+b+c)$ sine $\frac{1}{2}(a+b+c)-a$, *co-sec. b, co-sec c*; since $\frac{a+b+c}{2} - a$ is but another expression for the value $\frac{b+c-a}{2}$.

To find A by calculation.

a	66°	(§ *b.*)
Co-sec. b	44°	= 0.158229
Co-sec. c	30°	= 0.301030
	2)140°	
Sine $\frac{1}{2}(a+b+c)$	70°	= 9.972986
a	66°	
Sine $\frac{1}{2}(a+b+c)-a$	4°	= 8.843585
Twice cos. $\frac{1}{2}$ A =		2)19.275830
Cos. $\frac{1}{2}$ A =		9.637915 = 64° 15′ 5″
		2
		A = 128° 30′ 10″

§ *c.* Whence the rule. The rectangle under the co-secs. of the two containing sides, into the *product* of sine of $\frac{1}{2}$ the sum of the three sides by the sine of the same $\frac{1}{2}$ sum, *minus* the subtending side, is *twice* the cos. of half the required angle.

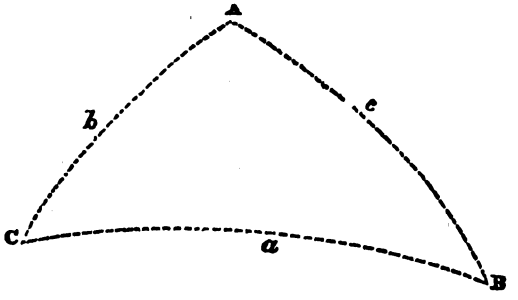
§ *d.* If tang. $\frac{1}{2}$ the required angle (§ 181. § *d.*) be used, the rule becomes: The rectangle under co-sec. half sum of the sides, and co-sec. that half sum minus the subtending side, into the *product* of the sine of the same half sum minus one containing side by sine same half sum *minus* the other containing side. } *Rule.*

§ *e.* Either angle being known, the other is determinable from the known ratio between the sines of sides and their opposite angles.

Digitized by Google

CASE VI.

§ 202. In which the three angles are given, viz:



A = 114°
B = 39°
C = 49°

To find the sides.

This problem is of but little practical importance to the navigator, for cases in which the three angles are the data seldom or never occur in practical navigation. There are several methods by which the required parts may be found; one of which, being general in its application, is thought sufficient.

To find either side as *a*.

§ *a*. This may be considered (§ 182. § *a*.) as a supplemental triangle to one whose sides are given, for which (§ 182. § *g*.) the following formula has already been investigated.

$$\text{Cos. } \tfrac{1}{2}\, a = \sqrt{\frac{\cos. \tfrac{1}{2}(A+B+C) - C,\ \cos. \tfrac{1}{2}(A+B+C) - B}{\text{sine B sine C}}}.$$

§ *b*. If for the divisors, sine B, sine C, we substitute their ar. cos. or reciprocals, (§ 109. § *f*.,) we shall have

§ *c*. Cos. $\tfrac{1}{2}\, a = \sqrt{\cos. \tfrac{1}{2}(A+B+C) - C, - \cos. \tfrac{1}{2}(A+B+C) - B,}$ *co-sec.* B *co-sec.* C.

By calculation.

§ *d*. $\dfrac{(A+B+C)}{2} - B = \dfrac{(114°+39°+49°)}{2} - 39° = 62°$ cos. = 9.671609

$\dfrac{(A+B+C)}{2} - C = \dfrac{(114°+39°+49°)}{2} - 49° = 52°$ cos. = 9.789342

Co-sec. B 39° - - 0.201128

Co-sec. C 49° - - 0.122220

Twice cos. $\tfrac{1}{2}\, a$ 2)19.784299

Cos. $\tfrac{1}{2}\, a = 38°\ 43'\ 50''$ = 9.892149

2

$a = 77°\ 27'\ 40''$

Digitized by Google

NAUTICAL ASTRONOMY,

§ 203. Is that part of astronomy which treats of the motions and of the positions of the heavenly bodies. A knowledge of these motions and positions is highly essential to the navigator; for it is by understanding them, that methods have been devised for determining latitude and longitude at sea, by means of observations made upon the heavenly bodies.

§ 204. The figure of the earth is that of an oblate spheroid. It resembles that which would be described by the revolution of a semi-ellipse about its minor axis. It is flattened in at the poles, and elevated towards the equator.

MOTION OF THE EARTH.

§ 205. For all the purposes of practical navigation, the earth may be considered as a perfect sphere; the sun as the centre of the universe, and the centre of motion in the planetary system; the fixed stars may be considered to be almost stationary, and immeasurably distant from the earth and from each other; and to be seen in the same relative positions, with regard to each other, from every part of the earth's orbit.

§ 206. The earth has two rotary motions; one about its axis, which produces day and night; the other in its orbit, and around the sun, which causes the seasons.

§ *a*. The latter is called the earth's annual, and the former its diurnal, motion.

§ 207. In its annual revolution around the sun, the earth describes the periphery of an ellipse.

§ *a*. The centre of the sun is in the plane, and at one of the foci of this ellipse, and the centre of the earth moves on its circumference.

§ 208. The axis of the earth is inclined, from a perpendicular to the plane of its orbit, nearly at an angle of 23° 28′.

§ *a*. If the earth's axis were perpendicular to this plane, there would be no change of seasons, or variation in the length of day and night; and at either pole there would be continuous daylight.

§ *b*. It is this angle of inclination which causes the *declination* of the sun.

§ *c*. In a northern winter the earth is nearer to the sun than it is in summer; but owing to the sun's declination, or the inclination of the earth's axis to the plane of the earth's orbit, the south pole is turned towards the sun during the former season, and the sun's rays, striking

Digitized by Google

the northern hemisphere more obliquely than they do in summer, are in consequence, spread over a greater surface, and are therefore less effective in producing heat.

§ 209. The earth revolves from west to east. It completes one revolution on its axis in a day, and one around the sun in a year.

§ 210. The periphery of the earth's orbit, like the circumference of every re-entering curve, contains 360°.

§ *a*. The earth completes one revolution in its orbit, in 365*d*, 5*h*, 48*m*, and 48*s*.

§ *b*. Therefore the motion of the earth in its orbit, in one day, is, as 365*d*, 5*h*, 48*m*, 48*s* is to 360° ; the ratio of which is 59′ 8″.

§ 211. An *astronomical*, *sea* or *civil*, day, is the time between two consecutive noons, or midnights.

§ 212. A *sidereal* day is the time between two consecutive transits of a star across the same meridian.

§ 213. The intervals of time from the passage of the sun and a star across, until their return to, the same meridian, are unequal. The difference between these intervals, results from the combined effect of the earth's motion about her axis, and in her orbit; for, during the interval between two consecutive transits of a star across the same meridian, the earth advances in its orbit (§ 210. § *b*.) nearly 59′ 8″; so that this meridian has to go 59′ 8″ more than one complete revolution around the axis of the earth, before it returns to the sun.

§ *a*. Thus, during the time in which the earth is making one complete revolution in its orbit, a star has one transit more than the sun has, across any proposed meridian.

§ *b*. Sidereal accelerates upon *mean* time about 9*s* 8‴ per mean hour, or 3 *m*, 55*s*, 9‴ from one transit of a star to the next transit of the same star. Therefore the mean time between two consecutive transits of any fixed star, is 23*h*, 56*m*, 4*s*, 09‴; and the sidereal time between two consecutive *mean* noons, is 24*h*, 3*m*, 56*s*, 56‴.

§ 214. The motion of the earth about its axis, is uniform: but the velocity of the earth in its orbit, is irregular. This irregularity is caused by the variation in the mutual action of the centrifugal and centripetal forces upon the earth.

§ *a*. The sidereal day is consequently of a uniform length, *nearly;* and the solar day varies with the angular velocity of the earth in its orbit.

§ *b*. This variation produces *equation* of *time*.

§ 215. *Apparent time* is the time which is deduced by calculation, from the bearing, or the altitude of the sun.

§ *a*. The time shown by a dial is apparent time.

§ 216. *Mean time* is the average of apparent time.

§ *a*. Watches, etc., are designed to keep mean time.

§ 217. *Equation* of *time* is the difference between mean and apparent time.

§ 218. If the motion of the earth in its orbit were uniform, describing equal arcs in equal times, there would always be the same length of time from one transit of the sun to another, across the same meridian; and apparent and mean time would always agree. But from noon to

Digitized by Google

the succeeding noon, there is sometimes more, and sometimes less, than 24 hours.

§ *a.* Twenty-four hours is the average, or mean of the time, in which, during one complete revolution of the earth in its orbit, the sun performs every one of its 365 transits across the same meridian.

§ *b.* This is the time which all good time pieces show. The time shown by them and the sun agrees only four times during a year; when this agreement takes place, then there is no equation of time.

§ 219. All astronomical calculations, such as those in the nautical almanac, etc., are computed for astronomical time.

§ *a.* Of those in the ephemeris, some are for *mean*, and some for *apparent* astronomical time.

§ 220. An astronomical day commences when the centre of the sun is on the meridian (say of Greenwich), and ends, when it returns to the same meridian.

§ *a.* An astronomical day is divided into 24 hours, which are reckoned in succession, from 1 up to 24.

§ 221. A civil day commences at the midnight, that *precedes* the beginning of the astronomical day.

§ *a.* A civil day is divided into two equal portions; the first is A. M.; it ends at noon, when the astronomical day begins: the latter is P M.; it ends at midnight, when the succeeding day begins. Each division consists of 12 hours.

§ *b.* Consequently, the day civil, is always 12 hours in advance of the day astronomical. Thus, Dec. 11th, 9*h* 34*m* 44*s* A M. is, according to astronomical time, Dec. 10th, 21*h* 34*m* 44*s*; and 16 hours of civil time, or Dec. 11th, 4*h* P. M., is Dec. 11th, 4*h*, according to astronomical time. Therefore, when the civil time is A. M., 12 hours added to it makes it astronomical time.

THE ECLIPTIC.

§ 222. The *ecliptic* is a great circle, the centre of which is that of the earth, and the plane of which coincides with the plane of the earth's orbit. Therefore these planes cut the axis of the earth at the same angle.

§ 223. The sun is always in the ecliptic.

§ *a.* Considering the earth to be stationary in its orbit, the sun appears to perform an annual revolution, moving around the earth, on the periphery of the ecliptic, and crossing the equator twice during the year.

§ 224. The ecliptic is divided into 12 arcs, of 30° each. These divisions, named and marked, are called the Signs of the Zodiac. They are—

§ *a.* Aries (♈), Taurus (♉), Gemini (♊), Cancer (♋), Leo (♌), Virgo (♍), Libra (♎), Scorpio (♏), Sagittarius (♐), Capricornus (♑), Aquarius (♒), and Pisces (♓).

§ *b.* The first six being north of the equator, are called *northern signs.*

§ *c.* The other six are south of the equator, and are called *southern signs.*

Digitized by Google

§ 225. The points in which the ecliptic (§ 223. § *a.*) crosses the equator, are called the *equinoctial points;* because, when the sun passes through these points, the days and nights are equal.

§ 226. The sun crosses the equator, and enters the first point of Aries, about the 21st of March. The sun then passes through Aries, Taurus, and Gemini, towards the north; and about the 21st of June, it reaches its greatest northern declination at the first point of Cancer, where it appears to be stationary for a while; it is then said to be in the *summer solstice.*

§ *a.* The first point of Cancer, is a *solsticial point.*

§ *b.* Returning thence, towards the south, the sun passes through Cancer, Leo, and Virgo, and completing its tour on the north side of the equator, it arrives, about the 23d of September, at the intersection of the ecliptic with the equator, when the day and night are again equal, and the sun is in the *autumnal equinox.*

§ *c.* Recrossing the equator then, the sun enters the first point of Libra, and continuing on towards the south, it *descends* through Libra and the succeeding signs, and reaches its greatest southern declination about the 22d of December; then it is at the first point of Capricorn, and again appears to stand still.

§ *d.* The sun is now in its winter solstice; and returning towards the north, it *ascends* through Capricorn, Aquarius, and Pisces, and entering the first point of Aries, completes one annual revolution; and so goes on to renew the seasons.

§ 227. The time from the sun's passing the first point of Aries, until its return to that point again, is about (§ 210. § *a.*) 365*d* 5*h* 48*m* 48*s*.

§ *a.* This is called a *solar*, or a *tropical*, year, and it is the year by which the seasons are regulated.

§ *b.* A solar, differs from a sidereal, year, about 20*m* 23*s*.

§ 228. A *sidereal year* is the time from the sun's leaving, until its return to, the same part of the heavens, or to the same fixed star.

§ *a.* A sidereal, is longer (§ 227. § *b.*) than a solar, year, on account of the *precession* of the *equinoxes*, which is a motion contrary to that of the sun through the signs.

§ *b.* While the sun is completing a revolution from left to right through the signs in successive order, they are moving in the contrary direction, or from right to left, and by the time the sun has returned to the first point of Aries, for instance, this point will have retrograded a little more than 51″; and, on account of this motion, the sun comes to this point sooner than it would have done, had the first point of Aries remained stationary.

§ 229. The *zodiac* is a belt in the heavens that extends 8° on each side of the ecliptic.

§ *a.* The orbits of all the primary planets are within the zodiac.

§ 230. The *primary planets* are Mercury, Venus, the Earth, Mars, Jupiter, and Saturn.

§ *a.* There are five other planets, but they cannot be seen with the naked eye. They are called *telescopic* planets.

§ 231. The points in which the orbit of a planet or comet cuts the ecliptic, are called *nodes.*

Digitized by Google

§ *a.* That node is called the *ascending node* (☊), through which the planet passes, as it crosses the ecliptic, going from the south to the north side of it.

§ *b.* The other point of intersection is called the *descending node* (☋).

EQUATOR.

§ 232. The *equator*, or *equinoctial line*, is a great circle, whose plane divides the earth into two equal parts.

§ *a.* These parts are called the northern and southern hemispheres.

§ *b.* The centre of the earth is the centre of the equator, and of *all the great circles used in nautical astronomy.*

§ 233. The *poles* (§ 123.) of the equator, also called the *Poles*, are two points on the earth, that are diametrically opposite to each other; each is 90° from the equator.

§ *a.* The one on the north side of the equator, is the *north pole*; and that on the south side, is the *south pole.*

§ 234. A straight line from one pole to the other, passes through the centre of the earth, and (§ 124.) is called the *axis* of the earth.

§ *a.* Around this axis the earth performs its diurnal revolution.

§ 235. From the best measurements the equatorial appears to be about 26 miles greater than the polar diameter of the earth. And the degrees of latitude increase in length from the equator towards the poles.

§ *a.* The surface of the earth (§ 204.) being flattened in at the poles, and elevated at the equator, its meridional curvature is less near the former than it is near the latter; consequently a degree of latitude near the poles contains more fathoms, feet, etc., than one at or near the equator.

§ 236. Suppose the plane of the equator to be extended to the heavens; it there forms the *celestial equator*, and its poles are the *poles* of the world.

§ 237. The latitude of places on the earth is measured from the terrestrial equator; and their longitude is measured on it.

§ *a.* In the heavens, the declination of the bodies are measured from the celestial equator, and their right ascension on it.

§ *b.* Declination and right ascension are, in the heavens, what latitude and longitude are on the earth.

§ 238. The sun crosses the equator twice in a year.

§ *a.* While the sun is on the north side of the equator, the sun is constantly visible from the north pole, and daylight continues there until after the sun recrosses the equator, when the sun goes below the horizon, and does not rise again, until (§ 226. § *d.*) completing its southern tour, it approaches the vernal equinox.

THE YEAR.

§ 239. The year, instead of being divided into seasons at the poles, may, more properly, be divided into day and night; for there is but one day and one night at each pole during the year.

Digitized by Google

§ *a.* At the north pole, the day commences about the 21st of March, when the sun crosses the equator, and continues until the sun recrosses the equator, which happens about the 23d of September, when night succeeds the day, and day begins at the south pole, and lasts until the sun again returns to the first point of Aries.

§ *b.* Owing to atmospheric refraction, the sun may be seen at either pole for several days previously to its rising above, and after it has gone below, the natural horizon.

§ 240. The morning and evening twilights at either pole, are together about two months and a half long.

§ *a.* When the sun crosses the *crepusculum*, the twilight begins and ends.

§ 241. *Crepusculum* is a small circle parallel to the horizon, and 18° below it.

§ 242. All small circles that are parallel to the horizon, are *almacanthers*.

§ *a.* To an observer at the north, or south pole, the horizon and the equator coincide, and the parallels of declination are almacanthers.

§ *b.* At the north pole, the crepusculum coincides with the parallel of the 18th degree of southern declination, which the sun crosses about the 29th of January, (near 51 days before it rises;) and on the 13th of November, (near 50 days after it has gone down.)

§ *c.* On account of such long twilights, the winter nights, in high southern or northern latitudes, are rendered less gloomy than they otherwise would be.

ZONES.

§ 243. The earth is divided into five *zones;* two frigid, two temperate, and one torrid.

§ *a.* The torrid zone is the largest; it extends to the parallels of 23° 28′ north and south latitude; consequently it is 46° 56′ broad.

§ *b.* The small circles which limit it, pass through the solsticial points, and are called *tropics*, from *trepho*, (Gr.); because, when the sun reaches the parallel of declination for 23° 28′ (§ 226. § *b.* and § *d.*) it appears to turn its course, and to recede from the pole which it was approaching, and to retrograde towards the direction whence it came.

§ *c.* That parallel which is north of the equator, (§ 226.,) is the *tropic* of Cancer.

§ *d.* And that on the south side of the equator, (§ 226. § *c.*,) is the *tropic* of Capricorn.

§ *e.* The sun is vertical twice a year, at every place within the tropics.

§ 244. Each of the temperate zones extends over 43° 4′ of latitude.

§ *a.* That on the north side of the equator, called the north temperate zone, extends from the tropic of Cancer to the arctic circle.

§ *b.* And the south temperate zone extends from the tropic of Capricorn to the antarctic circle.

§ 245. The *arctic* and *antarctic* are small circles, parallel to the equator, and 23° 28′ from the poles.

Digitized by Google

§ *a.* The arctic is about the north, and the antarctic about the south pole.

§ *b.* They are sometimes called the *polar circles.*

§ 246. The *frigid* zones are between the polar circles and the poles

LATITUDE.

§ 247. *Latitude* is distance on the earth, measured north or south, from the equator.

§ 248. *Meridians* are great circles, that are secondaries (§ 127. § *a.*) to the equator.

§ *a.* Therefore (§ 126. § *a.* and § 127.) they cut it perpendicularly, and intersect each other at the poles.

§ *b.* The arc of a meridian that is contained between a place and the equator, measures the latitude of that place.

§ *c.* The meridian of an observer passes through his zenith.

§ 249. *Parallels* of *latitude* are small circles parallel to the equator.

§ *a.* All places upon the same parallel have the same latitude.

§ *b.* And all places that are on the same meridian, are in the same longitude.

§ 250. *Circles of longitude* are meridians.

§ 251. *Elevation* of the *pole* is the distance of either pole above the horizon of any observer.

§ *a.* This distance is measured on the meridian of the observer; it is equal to his latitude.

LONGITUDE.

§ 252. *Longitude* is the distance, expressed in degrees, etc., between two meridians. It is measured on the equator, and east or west from any meridian.

§ *a.* A meridian from which longitude is measured, is called the *prime* meridian.

§ *b.* The location of this meridian is arbitrary. The French reckon the longitude of all places from the meridian of Paris; the Spaniards from Cadiz. The English use the meridian of the Royal Observatory at Greenwich for their prime meridian: and the Americans generally construct their charts from the meridian of Washington City.

§ 253. It is to be wished that all nations would fix upon one common prime meridian. One might be established from celestial phenomena, by which all that is arbitrary in its locality, might be made to disappear. La Place recommends the adoption of a universal first meridian, and suggests the propriety of selecting for this purpose, that meridian, upon which it was 12 o'clock when the sun entered the point of the vernal equinox in the year (1250) in which the apogee of the earth's orbit coincided with the solsticial point in Cancer. Such a universal meridian would pass about 8 miles west of Cape Mesurada on the Coast of Africa.

§ 254. The longitude of a place is measured on the arc of the equa-

Digitized by Google

tor, which is contained between the meridian of that place, and the prime meridian.

§ *a.* The angle at either pole, (§ 133.) which these two meridians make with each other, is equal to the longitude.

§ *b.* Consequently the arc of a parallel of latitude (§ 249.), which is intercepted between that place and the meridian of any other place, contains, in degrees, the difference of longitude between these two places.

§ *c.* The difference of latitude between two places, is the arc which is contained on the meridian of either place, between the parallels of latitude of these two places.

DECLINATION.

§ 255. *Declination* is the distance of a heavenly body from the equatorial plane.

§ *a.* Declination is north or south, according as the body is north or south of the equator. It is measured in the heavens, as latitude (§ 248. § *b.*) is on the earth.

§ *b.* The arc of the circle of declination or of right ascension, that is contained between the equator and the centre of the body, measures its declination.

§ 256. *Circles* of *right ascension* or of *declination* in the heavens, correspond with meridians of terrestrial longitude.

§ *a.* They cut the equator at right angles, and intersect each other in the poles of the world.

§ 257. *Parallels* of *declination* are small circles in the heavens, that are parallel to the equator.

§ *a.* They correspond with parallels of latitude on the earth.

§ *b.* The tropics (§ 243. § *c.* and § *d.*) are the parallels of the sun's greatest declination.

§ 258. *Polar distance* is the distance of any celestial body from either pole.

§ *a.* It is the arc of the circle of declination that is contained between the body and either pole.

§ *b.* The complement of the declination of a heavenly body, expresses its nearest polar distance.

§ 259. The *right ascension* of a body is the arc of the equator, which is between the first point of Aries and the circle of the declination of that body.

§ *a.* This arc is always counted in the order (§ 224. § *a.*) of the signs, and its divisions are expressed in hours, minutes, and seconds.

RIGHT ASCENSION.

§ 260. Right ascension in the heavens, is what longitude is on the earth. But the manner of reckoning the two is different.

§ *a.* Longitude is reckoned from the prime meridian as far as 180° both east and west.

§ 261. Right ascension commences to be reckoned from the first

Digitized by Google

point of Aries, and goes entirely around, in the direction in which the sun passes through the signs.

§ 262. *Horary angles* are those which meridians, or circles of declination, make with each other at the poles.

§ 263. The 6 *o'clock hour circle*, is that circle of declination (§ 256. § *a*) which cuts the equator and the horizon in the east and west points.

§ *a*. It is secondary to the equator and to the meridian of the observer.

§ *b*. Any circle of declination may be an *hour circle*.

§ 264. *Celestial latitude* is distance between the ecliptic and any body in the heavens; it is measured from the ecliptic, and upon a secondary (§ 127.) to it.

§ 265. The secondaries of the ecliptic, are circles of celestial longitude.

§ *a*. The arc of the circle of celestial longitude, that lies between the ecliptic, and a body in the heavens, measures in degrees, etc., the latitude of that body.

§ 267. The longitude of heavenly bodies is reckoned on the ecliptic, as right ascension is on the equator (§ 259.).

§ *a*. It commences at the first point of Aries, and is reckoned around in the direction in which the sun passes through the signs.

§ 268. The right ascension and longitude of an object are never the same, except when the body is on the solsticial colure, which cuts both the ecliptic and the equator at right angles, and passes through their poles.

§ 269. The *solsticial colure* is that circle of declination which passes through the solsticial points (§ 226. § *a*. and § *c*.).

§ 270. The *equinoctial colure* is the circle of declination, which passes through the equinoctial points (§ 226. § *b*.).

§ 271. The equinoctial and the solsticial points are the four *cardinal* points of the heavens.

HORIZON.

§ 272. The four *cardinal* points of the horizon are the east and west, and the north and south points.

§ *a*. The *east* and *west* are the points in which the equator and the horizon intersect each other.

§ *b*. The *north* and *south* are the points in which the meridian of the place cuts the horizon.

§ 273. Every observer has two horizons, one *rational*, the other *sensible*.

§ *a*. The eye is the centre of the latter, and is on the axis of the former.

§ 274. The *sensible horizon* is that circle which terminates the view upon an uninterrupted plane.

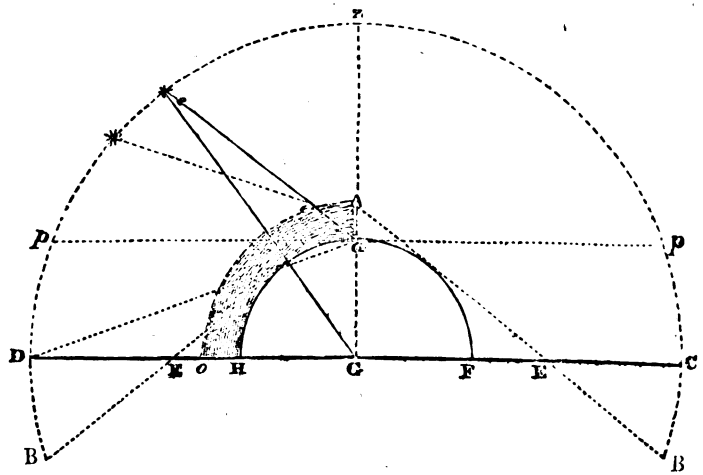
§ *a*. It is formed by the apparent meeting of the plane upon which we stand, with the concave expanse above.

§ *b*. It is a small circle, and is parallel to the rational horizon.

Digitized by Google

§ *c*. The circle which terminates our view at sea, is the sensible horizon.

§ 275. The *rational horizon* is a great circle; its plane passes through the centre of the earth, and its axis through the eye of the observer. Suppose H *a* F to be half of the earth, D Z C the concave blue which bounds the vision, and D H C the plane of the rational horizon. If an observer were placed at the centre (G) of the earth, the angle D G Z would show the altitude of an object in the zenith, at Z, from the rational horizon. If the observer were placed at the circumference (at *a*) of the earth, *p a p* would be the plane of his visible horizon, and the angle *p a* Z (= D G Z § 30.) would show the altitude of a body at Z, from the sensible horizon. But if the observer were placed at A above the surface of the earth, the angle B A Z (> D G Z) would show the altitude of Z from his sensible horizon.



§ *a*. When the eye is elevated above the level of the sea, (as at A,) the line of vision A B to a point B in the sensible horizon, cuts the plane C D of the rational horizon at an angle, D E B, which angle is called the *dip*. Consequently, when the eye is above the surface of the plane on which we stand, the sensible horizon is *below* the rational horizon.

§ *b*. The poles of the rational horizon are the zenith and nadir.

§ 276. The *zenith* is the point in the heavens which is directly over head.

§ *a*. Being a pole of the horizon, (§ 123.,) the zenith is 90° from the horizon.

§ 277. The *nadir* is the other pole of the horizon; it is in the lower part of the heavens, directly under our feet, and diametrically opposite to the zenith.

§ 278. *Azimuth* circles are secondaries (§ 127.) to the horizon;

Digitized by Google

cutting it perpendicularly, they intersect each other in the zenith and nadir.

§ *a.* They are also called *vertical* circles.

§ 279. The azimuth circle which cuts the horizon in the east and west points, is called the *prime vertical.*

§ *a.* The prime vertical of every observer, is secondary to his meridian.

§ 280. The altitude, and zenith distance of a heavenly body, are measured on its azimuth circle.

ZENITH DISTANCE, AND ALTITUDES.

§ 281. The *zenith distance* of a heavenly body is its distance from the zenith of the observer; thus, Z *s* (§ 275.) is the zenith distance of the star at *s*.

§ *a.* It is measured on the arc of the azimuth circle, which lies between the centre of that body and the zenith.

§ *b.* The *zenith distance* is *north* when the body is south of the observer.

§ *c.* And south, when the body is north of the observer.

§ 282. The *altitude* of a heavenly body, is its distance above the horizon.

§ *a.* The arc of the azimuth circle which is contained between the centre of a body and the horizon, measures the altitude of that body; thus, D *s* (§ 275.) is the altitude of the star at *s*.

§ *b.* The complement of the altitude of a body, gives its zenith distance.

§ 283. The altitude which is taken of the sun or moon, with a quadrant or sextant, is the observed *altitude* of one of the edges, called a *limb.*

§ *a.* The apparent altitude of the *centre* is found by applying the corrections, (which are laid down in the Nautical Almanac,) for the semidiameter of the body, to the apparent altitude of its limb.

§ *b.* And the *true*, is obtained from the *apparent* altitude of the centre, by applying to the latter, corrections for the parallax and refraction, which are also known by previous calculations.

§ *c.* The apparent and the true altitude of a body, are always measured on the same azimuth circle.

REFRACTION AND PARALLAX.

§ 284. The rays of light coming from the heavenly bodies strike the atmosphere obliquely, and entering from a rarer into a denser medium, are refracted, or *bent downwards;* this causes the body whence they emanate to appear higher up in its azimuth circle than it really is. Suppose * *e* (§ 275.) be a ray of light from *, and A *o* to represent the atmosphere; when this ray strikes the atmosphere, it will be refracted so as to reach the eye of the observer at *a*, in the direction *a e*, which makes * appear at *s*, above its true place.

Digitized by Google

§ *a.* Hence the apparent altitude of the sun or a star is always greater than the true altitude, unless the body be in the zenith.

§ 285. Parallax has a contrary effect; it acts in a direction opposite to that of refraction, and causes a body to appear *lower* down in its azimuth circle than it really is.

§ *a.* But the effects of parallax and refraction, though acting in contrary and opposite directions, seldom counterbalance each other, so as to make an object appear in its true place.

§ 286. The parallax of the moon is always greater than the refraction; and the moon always appears below its true place.

§ *a.* Hence the apparent, is always *less* than the true altitude of the moon.

§ 287. The *horizontal parallax* of a body, is the difference between the *true* and *apparent* altitude of that body, (supposing there be no refraction, when it is in the horizon.)

§ *a.* The horizontal parallax is equal to the angle at the body, which is subtended by the distance of the observer, from the centre of the earth; or which is the same, by the semidiameter of the earth.

§ *b.* The angle which this distance, or semidiameter, subtends, is greatest when the body is in the plane of the rational horizon; thus, the parallax of a body at D, (§ 275.) is the angle G D *a*; and the parallax of the same body, when at *s*, is G *s a*.

§ *c.* As the object rises above the horizon, the angle which this semidiameter subtends, is called *parallax* in *altitude;* it gradually decreases until the object reaches the zenith, when it vanishes.

§ *d.* The nearer the object is to the earth, the greater will this angle be at the centre. Hence the moon's parallax is greater than the sun's; and this greater than that of the fixed stars.

§ 288. The parallax of a body decreases from the horizon to the zenith, in the proportion of sine of the zenith distance (§ 281.) to radius.

§ 289. Owing to the effects of parallax and refraction upon the heavenly bodies (§ 285. § *a.*), they are never seen at their *true* altitudes except when in the zenith.

§ *a.* The altitudes at which the heavenly bodies are seen, are called their *apparent altitudes.*

§ 290. The *true altitude* of a heavenly body is that altitude at which it would appear, if seen from the centre of the earth.

Azimuths.

§ 291. The *azimuth* of a celestial body is the angle which is contained at the zenith, between the meridian of the place, and an arc of the azimuth circle, which passes through the centre of that body.

§ *a.* In north latitudes, the angle on the *north* side, and in south latitudes, the angle on the *south* side, of the arc of this azimuth circle, is called the azimuth.

§ *b.* Before a body crosses the meridian of the observer, its azimuth is east; after it crosses, its azimuth is west.

§ *c.* Thus, in north latitude, an azimuth is said to be *north*, so many degrees east, if the body be east of the meridian; or *N*, so many degrees west, if it have passed the meridian.

Digitized by Google

§ *d.* And in south latitude, the azimuth is reckoned in the same manner from the south point, to the east or west.

§ 292. The *amplitude* of a celestial object, is the arc of the horizon that lies between the east or west point, and the centre of that object when it is rising or setting.

THE NAUTICAL ALMANAC.

§ 293. The tables of the Nautical Almanac (§ 219.) give the mean and sometimes the apparent positions of the sun, the moon, the planets, and certain fixed stars, for Greenwich time. The declination and R. Ascension of 100 stars are given at pp. 444—447, for every 10th day. The equation of time (p. I, of each month,) and declination of the sun, etc. for every day; the lunar distances (p. XIII. to XVIII.) for every third hour; and the R. A. and Declination of the moon (p. V. to XII.) for every hour, etc.

§ *a.* Now, in order to take out the equation of time, declination, etc., at any other place, the first thing is to find out the Greenwich time that corresponds to the time at the place for which the correction is sought, and then find the correction required by a simple rule of proportion. Thus,

TAKING OUT THE EQUATION OF TIME.

§ *b.* To take out the equation of time for 9 A. M. (app. time,) Nov. 25th, 1844. Long. 75° W. Long. 75° = 5*h*. Therefore the Greenwich time for which the equation is required, is Dec. 25th, 2*h*. Now the equation of time, p. I, is decreasing at the rate of 19*s* a day, or 79‴ per hour. Therefore 79‴ × 2 = 1*s* 58‴ to be subtracted from 12*m* 41*s* 82‴, for the equation required.

§ *c.* To find the equation of time in long. 75° E. at 9 A. M. Nov. 25, 1844. The corresponding Greenwich time is 8 hours *before* the 25th, or Nov. 24th, 16*h*. The change per hour is 76‴. Therefore 76‴ × 8 = 6*s* .08 to be added to 12*m* 41*s* 82‴ = 12*m* 47*s* 90‴, the equation required.

TAKING OUT THE ☉'S DECLINATION.

§ *d.* To take out the sun's declination (p. I.) for long. 90° W. Nov. 26, 1844, at 10 A. M. : 90° = 6*h* — and 6*h* + 10*h* = 16*h* or 4 P. M. Greenwich time. The hourly change of Dec. (*increasing*) is 27″ 53‴. Therefore 27″ 53‴ × 4 = 1′ 50″ 12‴, which added to the Dec. on 26th, gives 21° 4′ 1″ 6‴, the Dec. required.

§ *e.* To take out the sun's declination for long. 105° E. at 8 A. M. (mean time) Decr. 3, 1844, (p. II.). Long. 105° = 7*h*. Therefore the time in 105° E. is 7*h* in *advance* of Greenwich time. And the Greenwich time for which the Dec. is required, is Dec. 2, 1 A. M., or 13 hours. The hourly change (p. I.) is 21″ 33‴, and the Dec. is in-

Digitized by Google

creasing, *i. e.*, it will be greater at noon of the 3d than it is 11 hours before; and if the change during the 11*h* be subtracted from 22° 10′ 40″ 2‴, we shall have the Dec. required. The hourly change (p. l.) = 21*s* 33‴ × 11 = 3′ 54″ 6‴ — 22° 10′ 40″ 2‴ = 22° 6′ 45″ 6‴ S.

TAKING OUT ☽'S DECLINATION.

§ *f*. To take out the moon's declination for Decr. 5, 1844, at 10 P. M. Long. 50° E. (p. VI.). Long. 50° = 3*h* 20*m*, which is in advance of Greenwich time. Of course, then, it will be 3*h* 20*m* before 10 P. M. at Greenwich; the time, therefore, for which the declination is required is 6*h* 40 P. M., Decr. 5. The change for 1*h* is 11′ 35″ 3‴; or for 10*m* it is 115″ 88‴, which multiplied by 4, and added to the declination at 6, (because it is increasing,) or multiplied by 2, and subtracted from the declination at 7, will give the required Dec. Thus, 115″ 88‴ × 4 = 7′ 43″ 5‴ + 10° 22′ = 10° 29′ 43″ 5‴ S; or 115″ 88‴ × 2 = 3′ 51″ 8‴ — 10° 33′ 35″ 3‴ = 10° 29′ 43″ 5‴ S.

§ *g*. To take out the moon's declination Nov. 21, 1844, at 6 P. M. Long. 32° W. The Greenwich time, therefore, is 8*h* 8*m* P. M. The Dec. (p. X.) at 8 o'clock, is 12° 54′ 53″ 7‴ N.; it is increasing, and the change for 10*m* = 91″ 35‴. What therefore is it for 8*m*?

TAKING OUT THE TIME OF LUNAR DISTANCE.

§ *h*. To find the time at Greenwich when the lunar distance of the sun was 78° 10′. Decr. 15, 1844, (p. XV.). By looking in the tables it will be seen that the lunar distance 77° 50′ 39″ occurred at 3 P. M., and that 79° 21′ 51″ occurred at 6 P. M. of the same day. Therefore the given distance occurred some time between 3*h* and 6*h*. Now if we take the difference—because it is the *least*,—between 77° 50′ 39″ and 78° 10′—and also the difference between the distance at 3 and at 6, and state the proportion: If this latter difference give 3*h*, what will the former give? the result will be the time to be added to 3*h* for the time required.

§ *i*. This is tedious, and p. XV. gives the proportional log. for the change during every three hours. If therefore we take the difference between the given distance and the one which *preceded* it, and from the proportional log. of this diff. subtract the prop. log. which is opposite said *preceding* distance, we obtain the prop. log. of the interval of time between the distance in the Nautical Almanac and the given distance; and this interval, added to the Greenwich time of the tabular distance, gives the time of the given distance.

Given as before ☉☾ = 78° 10′

3 P. M. (p. XV.)	77. 50. 39″	P. Log. =	2953
	11. 21	" =	1.2003
	P. Log. 0*h* 22*m* 24*s* =		0.9050
	3.		
	3*h* 22*m* 24*s* =	78° 10′ (☉☾)	

Digitized by Google

§ *j*. In the same way, Right Ascensions, etc. are also taken out.

VARIATION OF THE COMPASS.

§ 294. The variation of the needle is determined by means of azimuths, or amplitudes.

§ 295. The needle does not always point to the north and south poles. At some places it points to the east, and at others to the west, of the true north and south points.

§ *a*. Even at the same place, the polarity of the needle does not remain constant.

§ *b*. As to the direction in which the needle points, it is subject to certain periodical changes, which do not follow any known laws. At some places, after having pointed, for several years, to the eastward of the true north, it has gradually pointed nearer to the north point, until it has reached the due north and south points; then crossing the meridian; the needle has continued to turn more and more to the westward of the true north, until it has attained the maximum of its deviation for that place, when, after having remained stationary for a time, it commenced its return towards its former position.

§ 296. *Variation* of the compass, or as it is sometimes called, the *declination* of the needle, is its deviation from pointing to the north and south poles. The variation is therefore measured by the angle which the *magnetic* axis of the needle makes with the meridian of the place.

§ *a*. The variation of the needle is seldom or never constant even at the same place. Besides an annual change (§ 294. § *b*.) it has also a diurnal variation, which at Washington City, sometimes amounts to 40′, its mean diurnal change though is about 10′, the greatest variation occurring between noon and 2 P. M., the least about 5 hours before, or at 9 A M.

§ 297. The points to which the needle tends, are called the *magnetic* north and south points.

§ *a*. When the northern point of the needle, or the N. point on the compass card, points to the eastward, or to the *right*, of the true north, the variation is *easterly*.

§ *b*. And *westerly* when the same point points to the *left*, or to the westward of the true north.

§ 298. The true direction of the magnetic north point, is found by applying the variation, when it is easterly, to the *right* of the true north; and to the *left* of the *true* north, when the variation is westerly.

§ *a*. Thus, when the variation is one point easterly, the north point of the needle, or the N. point on the compass card, points N. by E. And it points N. N. W. when the variation is two points westerly.

§ *b*. Wherefore, knowing the magnetic bearing of any object, its true bearing may be determined, by applying the variation, when easterly, to the *right* of its compass bearing; and to the *left*, when the variation is westerly.

§ *c*. The true bearing of an object, that bears East per compass, is

Digitized by Google

E. by S. if the variation be one point easterly; but E. by N. if the variation be one point westerly.

§ 299. The cause of variation, as well as of the attraction of the needle, towards the poles, is unknown, except that it is caused by what is called *terrestrial magnetism.*

§ *a.* The subject of magnetism has of late years attracted the attention of scientific men very closely. Magnetic observatories have been established in different parts of the world, and the subject has been pursued with great industry and ingenuity. In these, needles are suspended by a few fibres of untwisted silk so as to give them freer motion; and they are read at the distance of several fathoms, that the animal heat of the observer, or any thing about his person, may not disturb the needle. The contrivance for reading is simple and beautiful, enabling the observer to detect changes of a few seconds, in the variation. But so far, these observations have thrown but little new light upon the subject to which they relate.

LOCAL ATTRACTION.

§ 300. The needle is subject to the influence of another power equally mysterious in its nature; it is called *local attraction.*

§ *a.* This attraction operates on ship-board, and with different effects in different latitudes, as well as in the different directions in which the vessel may be heading.

§ *b.* Its effects upon the needle become obvious by taking the bearing of a fixed point on shore, then swinging the ship entirely around, and observing at several different points of her heading, the bearing of said fixed point.

§ *c.* The effect of local attraction upon the compass, is not often taken into consideration by navigators, although on board of vessels in some latitudes, (as in the English channel), it is said to cause the needle to deviate several degrees. The loss of fleets has been ascribed to the neglect of this attraction, on the part of navigators.

§ *d.* In conducting surveys, and every day at sea for the detection of currents, particular attention should be paid to the effect of local attraction upon the needle. (See description of Az. Compass in the sequel.)

§ 301. A *magnetic* meridian is a great circle that passes through the magnetic north and south points, and through the zenith of the observer.

§ *a.* The needle, when subject to free motion, is always in the magnetic meridian. Therefore this meridian like the needle (§ 295. § *a.*) is constantly changing. And when the magnetic meridian of any place is referred to, its *mean* position is understood to be meant.

§ *b.* Magnetic meridians cross each other in the magnetic poles.

§ 302. The *magnetic* equator is (in *theory*) a secondary to all magnetic meridians.

§ 303. The *magnetic* prime vertical is a secondary to the magnetic meridian of the observer.

§ *a.* It passes through the zenith and the magnetic east and west points of the horizon.

Digitized by Google

§ 304. The *magnetic* azimuth of a celestial body, is an angle at the zenith, that is contained between the magnetic meridian of the observer and the zenith distance of the object, when its bearing is taken.

§ *a.* The magnetic azimuth (§ 291. § *b.*) should always be reckoned from the nearest pole, around towards the east, when the object is on the east side of the meridian of the observer; and to the west, after the object has crossed the meridian.

§ *b.* The advantage of reckoning the magnetic azimuth in this way, consists in having the true and magnetic azimuth always of the same name; *i. e.*, either both east, or both west.

§ 305. The *magnetic* amplitude of a celestial body, is that arc of the horizon, which lies between the centre of the body, when the body is in the horizon, and the magnetic east or west point, according as the body is rising or setting.

§ 306. Upon the magnetic equator, the needle assumes a horizontal position.

§ *a.* To the north or south of this equator, it points *downwards*, inclining towards the nearest magnetic pole, causing the

DIP OF THE NEEDLE.

§ 307. The angle of this inclination of the needle, below the plane of the horizon, is called the *dip* of the needle.

§ *a.* The maximum of the dip is at the magnetic poles, and the minimum, at the equator.

§ *b.* The dip, or the power, called the *vertical force* which causes it, like the variation, is ever changing: and there seems to be a close connection between it and temperature, for the dip is not only greater in winter than in summer, but when the needle is exposed to the changes of temperature, the greatest dip during the day generally occurs at the coldest hour, and the least at the warmest. The average dip at Washington City is about 72°, and the variation at this time 1° 35′ W.

§ 308. The variation of the compass is found by ascertaining the true and magnetic azimuths, or amplitudes, of any celestial object at the same moment.

§ *a.* The difference between them is the variation.

§ 309. The magnetic azimuth, or amplitude of a celestial object, at sea, is found by taking its bearing with an azimuth compass.

§ 310. The true azimuth or amplitude of a celestial object is determined by trigonometrical calculations.

§ *a.* The usual data for this operation, are the co-latitude of the observer, the zenith dist. and polar dist. of the object.

§ 311. In North Latitude; the variation is easterly, if the magnetic be less than the true azimuth, when the object is on the east side of the meridian; or the variation is easterly, if the magnetic be the greater azimuth, when the object is west of the meridian.

§ *a.* And in South Latitude; the variation is easterly, when the magnetic is the greater azimuth in the former, and the less in the latter case.

§ *b.* In each case, *mutatis mutandis*, the variation is westerly.

Digitized by Google

PROJECTION.

§ 313. *Stereographic projection* is the most useful, and being the most conformable, is the most simple mode of representing a sphere, or circles of a sphere, upon a plane.

§ 314. In stereographic projection the eye is supposed to be at some point on the surface of the sphere, and to see one half of the sphere.

§ *a.* The circle which terminates the vision is called, in projection, the *primitive circle.*

§ *b.* The eye is the centre of this circle, and is the *projecting point.*

§ 315. The diagrams for the purposes of nautical astronomy, in this treatise, are projected upon the plane of the horizon.

Plate 2. § 317. This Fig. is a stereographic projection upon the plane of the horizon, in lat. 40° north.

§ *a.* A, the projecting point, represents the centre of the horizon W N E S, as well as the zenith and the eye of the observer; P, the pole of the observer; P N (§ 251.) the elevation of the pole; W Q E (§ 232.) the equator; A Q (§ 248. § *b.*) the latitude of the observer; and A P the complement of his latitude; W A E (§ 279.) his prime vertical; N P S (§ 248. § *c.*) his meridian; A B *l* (§ 278.) the azimuth circle of the body whose altitude is taken; B *l* and A B (§ 280.) its altitude and zenith distance; *d e c* (§ 257.) the parallel of its declination; P B (§ 258. § *a.*) its polar distance, and P B H (§ 256. § *a.*) is an arc of its circle of declination; A P B (§ 263.) is the horary angle at which the body is; B A P (§ 291.) is its azimuth; N, E, S, and W, (§ 272.) are the cardinal points of the horizon; and W P E (§ 263. § *a.*) is the six o'clock hour circle.

§ *b.* It is easily conceived how it is, that, of all circles which cut the primitive circle of a projection, only that part of their circumference which is above the primitive, can be seen from the projecting point; and that 180° of every arc of these circles, that are great circles, is above (§ 125. § *a.*) the horizon or plane of projection.

§ *c.* And consequently that all of these arcs will appear in the projection to be more straightened out, or of less curvature than the primitive circle; and this curvature will be in proportion inverse to the obliquity with which their planes cut the plane of the primitive.

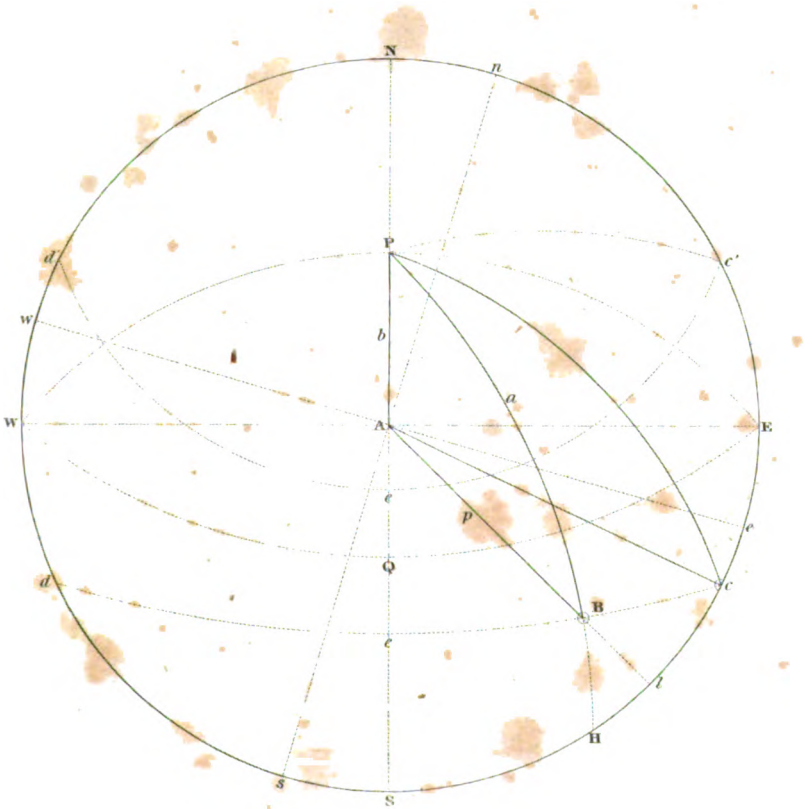
§ *d.* The less obliquely these planes cut the plane of the horizon, the more obliquely the observer at A looks upon them, and consequently the less their arcs appear to be curved, until, looking upon the edge of the planes of those which pass through his zenith, they appear as straight lines.

§ 318. In these projections, every great circle (N P S, W A E,) which passes through the zenith, is represented as a straight line.

§ *a.* And the length of every line (A N, A *l*, etc.,) included between the projecting point (A) and the circumference of the primitive, measures 90°, and is considered as the quadrant of a circle.

§ *b.* All of those circles which cut the plane of the primitive obliquely, and whose arcs (W Q E, P B, etc.) appear in the projection, to be of less curvature than the primitive, are called *oblique circles.*

Digitized by Google



Digitized by Google

Digitized by Google

§ *c.* And those circles, whose arcs (N P S, W A E,) pass through the zenith (§ 318.) are called *right circles.* } Plate 2.

§ *d.* With the horizon as the primitive circle; the meridian, (§ 248. § *c.*), prime vertical, (§ 279. § *a.*), and azimuth circles (§ 278.), pass through the zenith, and appear upon the plane of projection (§ 318.) as right circles.

AZIMUTHS.

How to take an azimuth and find the variation of the compass:

§ 320. Mount the azimuth compass on its tripod aft, and as far from the iron about the masts and sides of the ship as practicable, and drive a copper tack in the deck to mark the place of each foot, that the tripod may be always set in the same place, and be affected at every observation as nearly alike by the surrounding iron, as possible. Let the card down upon its centre, and when it becomes steady, note the heading of the ship by the azimuth and by the steering compass, to be recorded with the variation.

§ *a.* Place the shades, and let one observer take the altitude of the sun, while the other observes its bearing through the prismating eye-piece. When both are ready, let one call out MARK, and then record both altitude and azimuth. Repeat the observation several times, and take the mean as the correct observation. Compare with the steering compass again, remove the card, put it in its box, and take the instrument down. } *The Observation.*

§ *b.* Nov. 21st, 1844, in lat. 40° N., time A. M., took the following altitudes and magnetic azimuths of the sun:

Az.	Alt.	
N. 118° 45′ E	16° 25′ 30″	ship's head
" 119 20	16 36 00	Pr. S. compass, N. E.
" 120 10	16 52 30	do. Az. do. N. E. ¼ E.
3)358 15	3) 114 00	
119° 25′ = Obs. Az.	16° 38′	= Obs. Alt.
	10′ 25″	Correction.
	⊙'s True Alt. 16° 48′ 25″	

⊙'s semi-diameter 16′ 13″
Refraction - — 3′ 20″
Dip (§ 275. § *a.*) — 2′ 28″

§ *c.* The sun's parallax in alt. (§ 287. § *c.*) is omitted here because much greater errors are necessarily involved in the data. In the same way the variation may be found by observations upon the moon, a planet, or a star, but when the moon is used, its altitude should be corrected for parallax.

Digitized by Google

§ 321. Required from the foregoing observation the sun's true azimuth, and the variation of the compass, the declination being 20° S.?

§ 322. Now let W N E S, (§ 316. § *a.*) represent the horizon of the observer; A the centre of it, his zenith, and the place at which he stood to take the observation; *n* A *s*, the magnetic (§ 301.) meridian; and (§ 308. § *a.*) N A *n* is the variation.

§ *a.* The co-lat. (A P), the zenith, and the polar distance, (A B, P B) (§ 317. § *a.*) are the sides of the triangle A P B, and (§ 321.) are the given parts; and the azimuth P A B, is the required part; the value of it is determined according to case V, (§ 201. § *c.*)

§ *b.* In the formulæ for calculation,

P D, stands for polar distance.

Z D, " zenith distance.

Co-lat. " complement of the latitude of the place of observation.

§ *c.* The complements of what is given (§ 321. § *b.*) constitute the data of the proposed triangle.

§ *d.* *b* = 50° - = Co-lat.
p 73=° 11′ 35″ = Z D
=*a* 110° - = P D

To find the azimuth P A B, (§ 201. § *b.*)

§ *e.* *a*, or P D = 110°
p, or Z D = 73° 11′ 35″ co-sec. = 0.018959
b, or Co-lat. = 50° - co-sec. = 0.115746

Sum 2)233° 11′ 35″

½ Sum = 116° 35′ 47″ sin. = 9.951426
½ Sum ∽ P D = 6° 35′ 47″ sin. = 9.060224

2)19.146355

Cos. ½ P A B = 9.573177=68° 1′ 16″

2

P A B (the true azimuth, (§ 291. § *c.*) = N 136° 2′ 32″E
B A *n* (the magnetic do. (§ 304. § *a.*) = N 119° 25′ E

N A *n* = Variation (§ 311.) = 16° 37′ 32″E

Plate 2. § *f.* The difference between the true and magnetic azimuths (§ 308. § *a.*) (N A B—*n* A B=N A *n*) is the variation.

§ *g.* The true, being greater than the magnetic azimuth, the variation (§ 311.) is easterly.

§ *h.* And the steering compass being ¼ point, or 2° 48′ 45″ to the *West* of the azimuth compass, the variation by it is ¼ pt. *less.* There-

Digitized by Google

fore the variation to be applied to the steering compass is N. 13° 48′ 47″ E.

§ 323. There is another method (or rather the same applied to the complements of the data,) by which the true az. may be determined; and this method is more convenient in practice because it saves the trouble to inexpert calculators, of finding their Z. Dist. and *Co.* Lat.

2d Method. P. D. = 110°

Alt.	16° 48′ 25″	*sec.*	= 0.018959
Lat.	40°	*sec.*	= 0.115746
	2)166° 48′ 25″		
Cos. ½ sum	83° 24′ 12″		= 9.060242
Cos. (½ S. ∽ P. D.)	26° 35′ 48″		= 9.951425
			2)19.146372
Cos. ½ tr. azim.	68° 1′ 15″		= 9.573186
	2		
	Tr. azim. 136° 2′ 30″		

§ *a.* This difference of 2″ by the two methods is caused by the fraction of a second in the ½ *sum*, of which no account is taken.

§ *b.* From the 2d method, the rule is inferred:

§ *c.* Take the diff. between the P. Dist., and ½ the sum of the true Alt., the Lat. and P. Dist.; then cos. this ½ *sum*, plus cos. the diff. between it and the P. Dist., added to sec. the Alt., plus sec. the Lat., gives double the cos. of ½ the true azimuth. } *Rule.*

AMPLITUDES.

§ 324. When the magnetic and true amplitudes of a body are both north, or both south, the difference between them is the variation.

§ *a.* But when one of the amplitudes is north and the other south, they are of different names; and their sum is the variation.

§ 325. If the amplitudes be of the same name (§ 324.), and the *true* be the less northern, or the greater southern amplitude, the variation is easterly when the object is rising; and,

§ *a.* The variation is also easterly, when the object is setting, and the *true* is north and the greater, or south and the less, of the two amplitudes.

§ 326. If "*magnetic*" be read for "*true*" in the conditions above, the variation becomes westerly.

§ 327. If the amplitudes be of different names (§ 324. § *a.*), and the *true* be the northern amplitude, when the object is rising, or the southern amplitude when the object is setting, the variation is westerly.

Digitized by Google

§ *a.* The converse of these conditions makes the variation easterly.

§ 328. The true amplitude and declination of a body are always of the same name.

§ *a.* Therefore it is known by inspecting the declination, whether the true amplitude be north or south.

§ 329. Every object in the heavens always rises and sets to the north, or to the south of the east and west points, according as its declination is north or south;

§ *a.* The equator (§ 272. § *a.*) cuts the horizon in the east and west points; and a parallel of north or south declination, being (§ 257.) parallel to the equator, must therefore cut the horizon, (if at all,) to the north or south of the east or west points.

§ 330. A body (say the sun) rises and sets in the points, in which the parallel of its declination cuts the horizon.

Plate 2. § *a.* Thus the sun's declination being 20° S., it rises and sets in the points (*c* and *d*) in which the parallel (*d e c*) of that declination cuts the horizon.

§ 331. To an observer who is on the equator, the sun's declination at the time of its rising or setting, is its amplitude; for,

§ *a.* The equator is then the prime vertical, and that arc of the horizon which (§ 292.) measures the amplitude, coincides with the arc of the circle of right ascension, which (§ 255. § *b.*) measures the declination.

§ 332. The sun rises in the east and sets in the west, point, only twice in the year.

§ *a.* This happens at the moments in which the sun enters the first point of Aries, and the first point of Libra, for (§ 226. and § 226. § *c.*) the sun is then crossing the equator.

§ 333. To an observer at either pole, the horizon and equator coincide, and the sun does not set, while it is on that side of the equator, which is next to the observer. And,

§ 334. If the observer approach any point of the equator, that point will rise *above*, and the one diametrically opposite, will sink *below* the horizon as many degrees as the observer advances from the pole. And,

§ *a.* The observer will not see the sun go below the horizon, until his distance from the pole is greater than the sun's declination.

§ 335. When the latitude and the sun's declination are of the same name, the sun is not seen to set as long as its declination is greater than the co-latitude.

To take an amplitude and find the variation from it.

§ 336. When the sun is in the horizon the refraction (§ 284.) is about 33'; therefore as its diameter is about $32\frac{1}{2}'$, it is really in the horizon when it appears about its diameter above it. Wherefore the proper time for taking an amplitude is when the sun appears to be about one diameter above the horizon.

§ *a.* The magnetic amplitude of the sun is taken in the same way (§ 320.) as the Mag. Az.; also the heading of the ship both by the Az. and steering compass, as there prescribed.

Digitized by Google

TAKING THE AMPLITUDE.

§ 337. In lat. 40° N. the declination of the sun being 20° S., the magnetic amplitude at sunrise was E. 90° 53′ 32″ S., the heading of the ship by each compass being the same. Required the true amplitude, and the variation?

Demonstration.

§ 338. The place of the sun at the time of its rising (§ 330. § *a.*) is at the point (*c*) in which the parallel of its declination intersects the horizon; *w* A *e* (§ 303.) is the magnetic prime vertical; the arc E *c* (§ 292.) is the true, and *e c* (§ 305.) the magnetic, amplitude of the sun; and P A *c* is the triangle of the proposed problem, of which the sides are given, and P A *c* is the part required. The triangle (§ 142.) is quadrantal, of which the quadrantal side is A *c*, (the zenith distance.) Plate 2.

§ *a.* Now (§ 150. § *a.*) calling the quadrantal side (A *c*) radius, and the legs (P A, P *c*) angles, and the angle P A *c* a leg, the problem is an example under Case 4, (§ 173. § *b.*)

§ *b.* P A or co-lat. = 50° co-sec. = 0.115746
P *c* or P. Dist. = 110° cos. = 9.534052

Cos. P A *c* = 9.649798 = 116° 31′ 4″

§ *c.* Now (§ 133. § *a.*) the arc N E *c* is the measure of the angle P A *c*; and the arc E *c* (§ 52. § *a.*) is the complement of N E *c*, and (§ 292.) the sun's true amplitude.

§ *d.* E *c*, the sun's true amplitude = E 26° 31′ 4″ S
e c, the sun's magnetic do. = E 9° 53′ 32″ S

The variation = 16° 37′ 32″ E (§ 324.)

§ *e.* The amplitudes are both south, and the true is the greater; wherefore (§ 325.) the variation is easterly.

§ 339. Recurring to § 323.: it is evident that the calculation (§ 338. § *b.*) for determining the amplitude, may be rendered more convenient in practice, by an artifice similar to the one there used.

§ *a.* Lat. = 40° sec. = 0.115746
Dec. = 20° sine = 9.534052

Sine ampl. = 9.649798 = 26° 31′ 4″

Magnetic ampl. = 9° 53′ 32″

Variation = 16° 37′ 32″ E

Digitized by Google

Rule. { § *b*. Whence the rule for finding the amplitude. The rectangle under sine dec. and sec. lat. gives sine of the amplitude.
§ *c*. By this rule, Table VII. has been calculated.

To find the amplitude by this table.

Table VII. { § *d*. Find the lat. in the column marked "lat." at the side of the table, and where the line in which the lat. stands, meets the column at the top or bottom of which the declination is found, stands the amplitude. Thus, opposite lat. 40° and under Dec. 20°, p. 167, is 26° 31′, the amplitude.

SUNRISE.

§ 340. When the latitude of an observer, and the sun's declination, are either both north, or both south, the sun always rises before, and sets after, six o'clock.

§ 341. When the latitude and declination are of different names, the sun rises after, and sets before, six o'clock.

§ 342. When the sun rises in the east, or sets in the west, point of

Plate 2. { the horizon, the sun is (§ 272. § *a*.) on the equator, and (§ 263. § *a*.) in its six o'clock hour circle (W P E); and therefore it rises and sets at six o'clock.

§ 343. The time of sunrise subtracted from 12 o'clock, gives the time of sunset, when the points in which the sun rises and sets, are equidistant from the point at which it crossed the meridian.

§ *a*. This happens when the declination at sunrise, and at sunset, is the same.

§ 344. When the sun (§ 342.) rises and sets at six o'clock, it is also in the first point of Aries, or of Libra;

§ *a*. As the sun's declination increases, its right ascension (§ 259.) becomes greater, and the first point of Aries farther from the east point of the horizon, when the sun is rising; and,

§ *b*. The interval between sunrise and 6 o'clock, also increases.

§ 345. The time between sunrise and noon, in any latitude, may be determined by knowing the sun's declination.

§ *a*. This operation consists in finding the value of the horary angle A P *c*, which the circle (P *c*) of declination, in which the sun rises, makes (§ 263.) with the meridian (N P S) of the place.

§ 346. The value of this angle, (A P *c*,) like that of every other, is expressed in degrees; but it may be converted into time, in the proportion of 360° to 24*h*, which (§ 218. § *a*.) is the mean time in which the earth performs one of its diurnal revolutions.

Digitized by Google

§ *a*. $\frac{360°}{24} = 15°$; therefore the sun describes an horary angle of 15° in 1*h*; $\frac{1h}{15}$ or $\frac{60m}{15} = 4m$; wherefore the sun describes an horary angle of 1° in 4*m*; of 15′ in 1*m*; and of 15″ in 1*s*.

§ *b*. Whence the rule for converting longitude, degrees, etc., into time, and the reverse.

Time and Degrees.

§ 347. Divide the degrees by 15, for *hours;* the product of 4 and the remainder, is *minutes*, (*m*); the quotient of the minutes (′) by 15 is also *minutes*, (*m*); and the product of 4 and the remainder to this quotient, is seconds (*s*); also the quotient of the seconds (″) by 15 is seconds (*s*) of time.

§ 348. The product of hours by 15, and the quotient of the minutes (*m*) by 4, are *degrees;* the product of the remainder of the minutes (*m*) by 15, and the quotient of the seconds (*s*) by 4, are *minutes* (′); and the product of the remaining seconds (*s*) by 15, is *seconds* (″).

§ *a*. The first two and last two columns of Tables II., show (with the hours at the bottom or top,) the value in time of the degrees and minutes which stand nearest to them.

§ *b*. And these columns may be used for finding the logarithmic value of hours, minutes and seconds, as well as for converting degrees, etc., into hours, etc., and vice versa. Therefore in the solution of problems, in which a given or required part consists of hours, etc., these need not be commuted in the process of solution, into degrees, etc.; but may be operated with under the denomination of *time*, and thus save the trouble of substituting their value in degrees, etc.

§ *c*. Thus, to take from the tables the log. of 4*h*, 20*m*, 40*s*; 4*h* is found at the right hand *bottom* corner of the tables; 20*m* is found in the right hand (*m*) column; and above 20*m*, 40*s* is found in the (*s*) column on the same side; opposite to 40*s*, and in the column which has the required precept at the *bottom*, is the required log.; thus, log. sine 4*h* 20*m* 40*s* = 9.957863.

§ *d*. The time corresponding to any log. is taken from the tables according to the directions under § 103. given for taking out the degrees, etc., for a log. sine, etc. Thus, the value in time of log. sine 9.618004 = 1*h* 38*m* 4*s*. The log. 9.618004 is found in the column marked (sin.) at the *top*. In the left hand column (*s*) of the page, and opposite to 9.618004, is 4*s*; above 4*s* in the (*m*) column is 38*m*, and at the top of the page on the same side is 1*h*.

§ *e*. The small columns marked (diff.) show the difference which 1*s*. or 15″ make in the log. sine, etc. of an arc or angle.

§ *f*. To convert 33° 10′ into hours, etc.; in juxta-position with 33° is 2*h*; and in the left hand columns, 10′ is opposite to 40*s*; and above 40*s*, is 12*m*; then 33° 10′ = 2*h* 12*m* 40*s*.

Examples.

Digitized by Google

§ *g*. To convert $5h\ 20m\ 28s$ into degrees, etc.; $5h$ is found at the bottom, and $20m\ 28s$ in the right hand columns. In juxta-position with $5h$ is 80°, and above $20m$, but opposite to $28s$, stands $7'$ in the (') column; then $5h\ 20m\ 28s = 80°\ 7'$.

The lat. and dec. being given, to find the time of the sun's rising or setting.

§ 349. At sunrise or sunset, the sun is in the horizon, and consequently (§ 276. § *a*. and § 281.) its zenith distance is 90°.

§ *a*. Wherefore, the triangle (§ 142.) is quadrantal, A P *c* is the required, A P and P *c* the given parts: the solution is similar to that used (338. § *b*.) for finding the amplitude. Let the dec. be 20° S., and the lat. 40° N. as before.

Plate 2.

§ 350.

P *c* = P. dist. 110° cot. = 9.561066 (§ 171. § *a*.)
P A = Co-lat. 50° cot. = 9.923813

Cos. A P *c* $4h\ 48m\ 52s$ = 9.484879

§ *a*. $4h\ 48m\ 52s$ ∽ $12h$ (noon) = $7h\ 11m\ 8s$ the *apparent* time (§ 215.) of day at sunrise. Or by using the supplement, we should have obtained the time $7h\ 11m\ 8s$ directly from the tables.

§ *b*. If the declination were 20° N., $4h\ 48m\ 52s$ would be the apparent time of day at sunrise, and its supplement, or $7h\ 11m\ 8s$ the apparent time of sunset, and *vice versâ*.

§ *c*. The angle *c* P N, or the supplement (§ *a*.) of *c* P A expresses the time that has elapsed from midnight to sunrise. And that is the time from which the hours of A. M. are reckoned.

§ 351. This angle (§ 263.) is always greater than $6h$ or 90° when the lat. and dec. are of different names.

§ *a*. But less when of the *same* name.

§ 352. Therefore, bearing these two precepts in mind, and recollecting that the cot. of the P. dist. and co-lat. is the same as tang. of the lat. and dec., we may obtain a more convenient formula for practice. Thus:

FORMULA.

§ *a*.

Dec. 20° tang. = 9.561066
Lat. 40° " = 9.923813

Cos. A P *c* (§ 351.) 9.484879 = $7h\ 11m\ 8s$

Digitized by Google

§ *b*. Whence the rule: Tang. of dec. and lat. is cos. time of rising and setting (§ 351. and § 351. § *a*.) } *Rule.*

§ 353. By this rule Table VIII. was calculated. It shows the apparent time at *sunrise*, when the lat. and dec. are of the *same* name; and the apparent time of *sunset* when the lat. and declination are of *different* names; for (§ 343.) the time at sunrise subtracted from 12*h* shows nearly the time at sunset. In the Table, the time from sunrise to 12 o'clock is supposed to be always equal to the time from noon till sunset. } Table VIII.

§ *a*. *How to use this Table.*

Trace the line on which the given lat. is found at the side, across to the column at the top and bottom of which the given declination stands, the time in this column and on that line is the time required. Thus the line on which lat. 40° crosses the column of dec. 20°, the time 7*h*. 11*m*. stands.

§ *b*. 7*h* 11*m* therefore (§ 350. § *b*.) is the time of sunset or sunrise, according to the precept at the head of the Tables.

§ 354. The length of the days and nights may be determined by means of the problem (§ 351.); for doubling the time from sunrise till noon, gives the time that the sun remains above the horizon; and,

§ *a*. Subtracting this time from 24, gives the length of the night, or the time that the sun is below the horizon.

THE PLANETS, MOON, ETC.

§ 355. A satellite is a body that revolves around a planet, as the centre of one of its motions, and also revolves with that planet around the sun.

§ *a*. The moon is the earth's satellite.

§ 356. Mercury and Venus, (§ 230.) are called *inferior* planets, because their orbits are between the earth's and the sun.

§ 357. Mars, Jupiter, Saturn, Herschel, etc., (§ 230. § *a*.) are *superior* planets.

§ *a*. Their orbits are further than the earth's is, from the sun.

§ 358. Jupiter has four satellites, which, revolving with different radii around its centre, accompany it in its revolutions around the sun.

§ *a*. As they revolve in their orbits from west to east, they pass behind Jupiter; and as they pass in front of it, they cross its disc. From the frequency of these passages, (called eclipses,) and the celerity of the motion of the satellites, their eclipses with Jupiter furnish excellent opportunities for ascertaining longitude when the observer is on shore. The satellites cannot be seen with the naked eye, and are of no use for ascertaining longitude at sea, because telescopes for observing their immersions and emersions, cannot be used on ship-board on account of the motion of the vessel.

Digitized by Google

DEFINITIONS.

§ *b.* When Jupiter is nearly in conjunction with the sun, the satellites cannot be seen at all.

§ 359. The moon moves from west to east in its orbit, around the earth.

§ *a.* The average, or mean time in which the moon performs one revolution in its orbit, is 27*d* 7*h* 43*m* 5*s*; this is called a *periodical month.*

§ *b.* The moon performs, in nearly the same time, one revolution on its axis, by which means the same side of the moon is always presented towards the earth.

☽'S MOTION AND PHASES.

§ 360. At the same time every day, the moon is seen about 13° 10′ 30″ further to the east than it was the day preceding.

§ *a.* This gives the moon an hourly motion with regard to the sun, or fixed stars, of about 32′ 56″; and makes the lunar about 49*m* longer than the solar day.

§ 361. When the moon presents a round, illuminated disc towards the earth, the latter is between the sun and the moon.

§ *a.* The moon is then about the point in its orbit at which it attains its greatest distance from the sun; and is said to be in *opposition* with the sun.

§ 362. At new moon, the moon is nearest to the sun; being between it and the earth.

§ *a.* The moon is then in *conjunction* with the sun.

§ *b.* The interval between two consecutive new or full moons is about 29*d* 12$\frac{3}{4}$*h.*

§ *c.* This interval of time is called a synodical month, to distinguish it from a periodical month (§ 359. § *a.*).

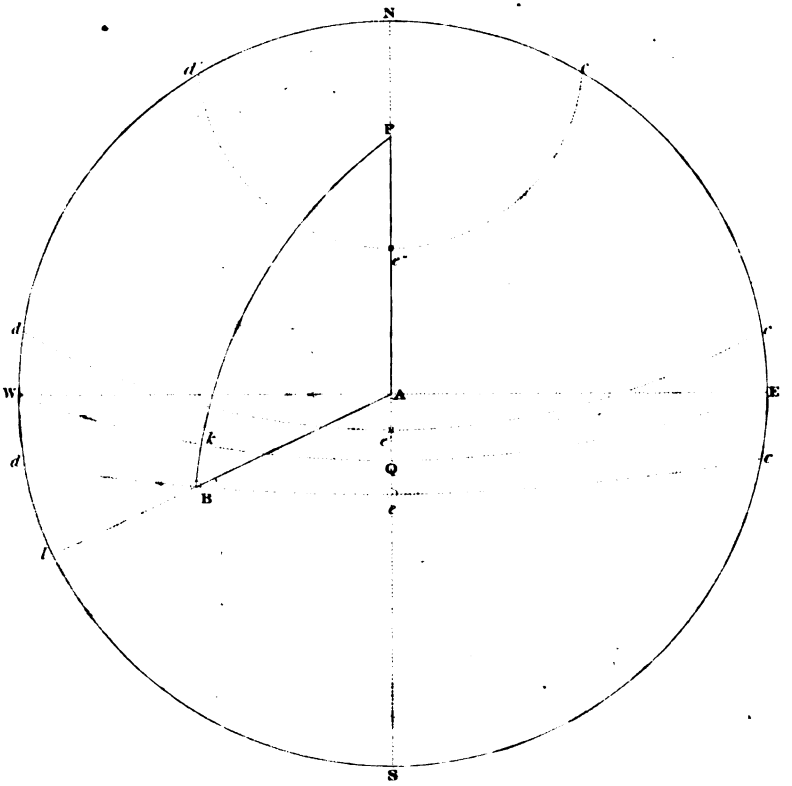
§ *d.* The difference between the periodical and synodical month is caused by the motion of the earth in its orbit around the sun; for by the time the moon returns in its orbit to the same place in the heavens, and is again in the position with regard to the fixed stars, which it had occupied 27*d* 7*h* 43*m* 5*s* (§ 359. § *a.*) before, the earth will have advanced in its own orbit, and the moon will have to continue on in its orbit, about 2*d* and 5*h*, before it overtakes the earth and occupies the position, with regard to the earth and the sun, and presents the same appearance, which it did when the two months commenced together.

§ 363. The light of the moon is reflected from the sun.

§ *a.* And the different appearances of the moon's figure, called *phases*, are caused by the enlightened part of the moon being turned more or less towards the earth.

§ 364. When the moon, passing between the earth and the sun, crosses the straight line which joins their centres, the whole of its unenlightened side is turned towards the earth; then it eclipses the

Digitized by Google



Digitized by Google

§ *a*. The amount of aberration must always be added to the sun's *apparent* longitude, in order to obtain the *true* longitude of the sun.

§ *b*. The longitude of the sun, given in the ephemeris, is *apparent*.

§ 378. *Radius vector* is a line supposed to join the centres of a planet and the sun.

§ *a*. The logarithm of "the radius vector of the earth" is the logarithmic value of the earth's radius vector; the semi-axis major of the earth's orbit being taken as the base, or unity, in the logarithmic scale.

TIME OF DAY.

Plate 3. § 379. In the triangle P A B are comprised the elements necessary to the operation of finding, by trigonometrical calculation, the apparent time of day.

§ *a*. B P A, (§ 263.), is an horary angle, and if any three parts of the triangle in which it is, be given, the value of B P A is at once determinable.

§ 381. The primitive data, in the problem for finding the time of day by an observation with the sextant, are usually the latitude of the observer, and the altitude and declination of the body under observation;

§ *a*. The complements of which form the triangle (B A P) of the problem.

§ 382. By inspecting the triangle of the problem proposed, it appears evident, that the horary angle (A P B) expresses the interval of time that elapses between the taking of the observation, and the transit of the body, (say the sun), across the meridian of the observer.

§ *a*. The time thus deduced is *apparent* time.

§ 383. If the observation be made in the forenoon, the value of the horary angle must be subtracted from 12*h*, in order to find the apparent time of day.

§ *a*. But if the time be P. M. the value of the horary angle expresses the apparent time of day when the altitude was measured.

§ 384. This problem, coming under Case V., (§ 201.), may be solved by either of the methods of solution there shown.

§ *a*. But as it is a rule, in the application of theory to practice, (and one too, which is highly important in navigation,) to combine facility of design with readiness of execution, a solution of the problem after the formula, § *b*. (§ 201.), will be given, in order to show thereby a process of solution less circuitous; by which process the problem under consideration may be solved.

§ 385. In lat. 20° N.; the observed altitude of the sun's lower limb,

Plate 3. in the afternoon, was 29° 29′ 50″; and its declination was 10° 20′ south. To find the time of day.

§ *a*. First to find the true altitude of the sun's centre.

EXAMPLE.

§ *b.* Obs. alt. ⊙ = 29° 29′ 59″
⊙ Semi-diam. = 15′ 47″

⊙'s app. alt. = 29° 45′ 37″ (§ 283. § *a.*)
Refraction (§ 384.) = 1′ 37″ (Table IX.)
Dip = 4′ (§ 275. § *a.*)

True alt. = 29° 40′ (§ 283. § *b.*)

§ *c.* To find the time of day.
B A, or Z. Dist. = 60° 20′
P A, or Co-lat. = 70° 00′ co-sec. = 0.027014 (§ 201. § *b.*)
P B, or P. Dist. = 100° 20′ co-sec. = 0.007102

2)230° 40′

½ sum = 115° 20′ sin. = 9.956089
(½ sum ∞ Z. Dist.) = 55° 00′ sin. = 9.913364

2)19.903569

Cos. ½ A P B = 9.951784 = 1*h* 46*m* ½*s*

2

Horary angle A P B = 3*h* 32*m* 1*s*

This time (§ 383. § *a.*) is P M., and is *apparent* time.

§ 386. The data of the problem may be operated upon, more directly, by using the lat. and alt., instead of their complements. Thus:

§ *a.* Alt. = 29° 40′
Lat. = 20° 00′ sec. = 0.027014
P. D. = 100° 20′ co-sec. = 0.007102

2)150° 00′

½ sum = 75° 00′ cos. = 9.412996
(½ sum ∞ Alt.) = 45° 20′ sin. = 9.851997

2)19.299109

Sin. ½ A P B = 9.649554 = 1*h* 46*m* ½*s*

2

Horary angle A P B = 3*h* 32*m* 1*s*

Whence the general rule for practice:

Digitized by Google

Rule. § 387. Take the difference between the true alt., and half the sum of the lat., P. dist., and alt.; then the *product* of the sine of this difference, and cos. of said half sum, *multiplied* by the *product* of sec. of lat., and co-sec. of P. dist., is the sine of half the horary angle.

§ *a.* The time thus found being apparent time, may be converted into mean time (§ 217.), by applying to it the equation of time, according to the precept given with the equation of time in the Nautical Almanac, p. I., or in Table XX.

§ *b.* App. time (§ 385. § *c.*) 3*h* 32*m* 1*s* P. M.
Equation of time — 13*m* 50*s*

Mean time = 3*h* 18*m* 11*s*

§ *c.* By comparing the mean time thus found, with the time shown by a chronometer, or other time-piece, when the altitude was measured, the error of the time-piece is obtained.

§ *d.* If this time-piece be regulated for a prime meridian (which is the case with chronometers) the difference between the true chronometrical, and the mean, time found by observation, expresses in *time* the difference in longitude between said prime meridian and the place of observation.

§ *e.* This difference in time being converted (§ 348. § *g.*) into degrees (°), minutes (′), etc., expresses the longitude of the observer.

§ 388. In the same way, the horary angle of the moon, of a planet or a fixed star, may be found. But the time thus found, being sidereal time, (§ 212.) has generally to be converted into mean time (§ 213. § *b.*)

EXAMPLE.

§ *a.* January 2, 1845, P. M., long. 6*h* (90°) west of Greenwich, Aldebaran being east of the meridian, its altitude as taken from an artificial horizon, was 60° 31′ 20″. To find the mean time of the observation.

§ *b.* The star appears as much below as it really is above the horizon, therefore the altitude observed is double the apparent alt.

Digitized by Google

2)60° 31′ 20″ = Obs. Alt. Star.

Ap. alt. = 30° 15′ 40″

Tr. alt. 30° 15′ 00″
Lat. 39° sec. = 0.109497 (§ 387.)
P. dist. 73° 48′ 27″ co-sec. = 0.017579 (N. A. P. 452.)

Sum 2)143° 3′ 27″

½ sum 71° 31′ 43″ cos. = 9.500828
(½ sum ∽ alt.) 41° 16′ 43″ sin. = 9.819360

2)19.447264

Sin. ½ horary angle $2^h\ 7^m\ 48\frac{1}{2}^s$ = 7.723632

2

Hor. angle A P B = $4^h\ 15^m\ 37^s$, which is the time to } Plate IV.

Time by a Star.

elapse before Aldebaran comes to the meridian.

§ *c.* Now (P. 452, Naut. Almanac) Aldebaran would cross the meridian at $4^h\ 27^m\ 4^s$, sid. time; wherefore, if we apply the horary angle, or the star's distance in *time* from the meridian to the star's right ascension, or the sid. time when it is to cross the meridian, we shall have the sid. time of observation, or the right ascension of the meridian, as it is called. Thus,

Right ascension of Aldebaran $4^h\ 27^m\ 4^s$ 28‴
Horary angle do. 4. 15. 37.

$11^m\ 27^s$ 28‴

§ *d.* Had this star been precisely at the same altitude, but *west* of the meridian, we should have added the horary angle to the time of its crossing the meridian, and thus the sid. time of obs. would have been $8^h\ 42^m\ 41^s$ 28‴ instead of $11^m\ 27^s$ 28‴.

§ 389. Now the sidereal time at mean noon, or when the hands of a correct mean time clock at Greenwich showed $0^h\ 0^m\ 0^s$, on January 2, was $18^h\ 47^m\ 55^s$ 42‴. (N. A. p. II.)

§ *a.* But (§ 213. § *b.*) sidereal time accelerates upon mean time about $3^m\ 56\frac{1}{2}^s$ in 24 hours; and the place of observation is 6 hours (§ 388. § *a.*) or ¼ day from Greenwich. Therefore $3^m\ 56\frac{1}{2}^s \div 4$ (= 59^s 12‴) added to the time of the Greenwich transit, will give the sid. time, or $18^h\ 48^m\ 54^s$ 54‴ when it was mean noon at the place of observation.

§ *b.* The difference, therefore, between the sid. time of observation and the sid. time when it was mean noon, will give the sid. time that had elapsed from noon till the observation was made. Thus,

Digitized by Google

Time by a Star.

R. A. merid. (§ 388. § c.), or sid. time of obs. $0^h\ 11^m\ 27^s\ 28'''$
Sid. time at mean noon $18^h\ 48^m\ 54^s\ 54'''$

$5^h\ 22^m\ 32^s\ 74'''$

§ *c.* Now $5^h\ 22^m\ 32^s\ 74'''$ is the sidereal time that has elapsed since mean noon, and the mean time that corresponds to 5^h etc. of sid. time will be the mean time of observation; and as the difference between mean and sid. time (§ 213. § *b.*) is $3^m\ 56\frac{1}{2}^s$ for 24 hours, the simple proportion $24^h : 3^m\ 56\frac{1}{2}^s :: 5^h\ 22^m\ 32^s\ 74''' :—$; gives $0^m\ 52^s\ 85'''$ as the correction.

§ *d.* Tables XIV. and XV., like those in the Nautical Almanac, are calculated upon this principle. They contain the equivalent of every hour, minute and second, etc., of sid. time in mean time, and the reverse.

Sid. Time 5^h	-	- =	$4^h\ 29^m\ 10^s\ 85'''$	Mean Time.
22^m	-	=	21. 56. 39	"
$32^s\ 74'''$		=	32. 65	"
Mean time of obs.		=	5. 21. 39 .89'''	

§ *e.* In taking the difference (§ *b.*) between the sid. time of observation, and the sid. time at mean noon, the sun is considered to be in advance when the right ascension of the meridian (§ 388. § *e.*), subtracted from the sid. time at noon, (borrowing 24^h if necessary,) is less than 12^h.

§ *f.* But when the sidereal time at noon (p. II. N. Almanac), subtracted from the right ascension of the meridian (also borrowing 24^h if necessary), is less than 12^h, then the sun is to the east, and the meridian is considered as being in advance of the sun as to *Rt. As.*

EXAMPLES.

Sid. into Mean Time.

§ *g.* To find the mean time that corresponds to 14^h sid. time, Jan. 2, 1845.

$18^h\ 47^m\ 55^s\ 42'''$ sid. time at *mean* noon (p. II. N. Almanac.)
14 R. A. meridian (§ 388. § *c.*)

4		=	$3^h\ 59^m\ 20^s\ 68'''$ (Table XV.)
47			46. 52. 30
	55^s		54. 85
	$42'''$		41
			$4^h\ 47^m.08^s.24'''$

Now it was noon at 18^h, etc., sid. time of January 2; therefore it wanted 4^h, etc., to noon of that day; hence (§ 221.) the mean civil time required is Jan. 2d, $7^h\ 14^m\ 51^s\ 76'''$ A. M.

EXAMPLE II.

LONGITUDE BY CHRONOMETER.

§ 390. The whole doctrine of determining longitude, consists in knowing the time of day at any two places at the same instant.

§ *a*. This is what is determined by every practicable method of finding longitude; whether it be by means of rockets, eclipses, occultations, lunar observations, or chronometers.

§ 391. The time of day at the prime meridian when an eclipse, occultation, or lunar distance, occurs, is set down in the ephemeris; and the time of day at any other place when the same eclipse, etc., occurs, is determined, either by well regulated time-pieces, or by observations.

§ *a*. And the difference between these times, (§ 389. § *b*.), gives the longitude, in *time*, of the observer.

§ *b*. The longitude is west, when the *prime meridian* (Greenwich, § 252. § *c*.) time is in advance of the time of day at the observer.

§ *c*. But if the observer's time of day be in advance of the Greenwich time, his longitude is east; for it is evident that the sun must cross his meridian, before it does that of Greenwich, and consequently, that Greenwich must be to the westward.

§ 392. Chronometers are generally regulated so as to show the mean time of day at Greenwich, after applying their error.

§ *a*. But they are subject to variations from change of temperature, etc., and from other causes, and cannot be regulated so as to show at all times, the true time of day at Greenwich, or at any other prime meridian.

§ 393. The difference between the time shown by the face of a chronometer, and the mean time of day at Greenwich, is called "the error of chronometer."

§ *a*. The daily variation of this error is "the rate of chronometer."

§ 394. The rate of chronometer is found by noting the difference between mean time, and the time shown by the face of the chronometer, on any day; and after several days, noting again the difference between the mean and the chronometer time.

§ *a*. The difference between these two *differences*, (called "comparisons,") shows the time which the chronometer has gained, or lost, from the first to the last comparison.

§ *b*. And the quotient of this gain or loss, by the number of days that may have elapsed between the two comparisons, is the daily gain or loss, or rate, (§ 393. § *a*.) of the chronometer.

§ 395. The error (§ 393.) being applied to the chronometer time, with the precept of *plus* or *minus*, according as the chronometer is fast or slow, of Greenwich time, gives the mean time of day at Greenwich.

Digitized by Google

§ *a.* And the *rate* of the chronometer being applied to the chronometer's error yesterday, with the precept +, or —, according as the *rate* is *increasing* or *decreasing*, gives the chronometer's error for to-day.

§ *b.* Before the chronometer is rated, the mean time of day at Greenwich for rating it, is found by turning the longitude of the observer, (§ 347.) into time; and,

§ *c.* Adding this time to the observer's mean time of day, if he be in west long;

§ *d.* And subtracting it from his mean time of day, if he be in east longitude.

§ *e.* Ten or twelve days previous to the sailing of the vessel, will generally serve for keeping her chronometer under comparison, in order to find its error, and ascertain its rate.

§ *f.* But after sailing, the rate should be compared, (and corrected if necessary,) as often as opportunities for making comparisons occur.

RATING BY EQUAL ALTITUDES.

§ 397. It is evident that a star which does not vary its declination is exactly as far from the meridian one hour before transit as it is one hour after. Thus, the distances A B and A H being equal, the altitude and hour angle of a star at B and H are equal. Plate IV.

§ *a.* Hence we infer that at the same horary angle, the same star is always at the same altitude.

§ *b.* Therefore the rate of a chronometer may be determined *without calculation*, by equal altitudes of the same star, taken in the same night both E. and W., or on different nights either E. or W.

EQUAL ALTITUDES WHEN THE STAR IS E. OR W.

§ *c.* Select some star of convenient altitude that bears nearly E. or West; take its altitude from an artificial horizon; note the time by the chronometer; clamp the sextant at the altitude; and put the instrument away carefully in its box. Now, (§ 213. § *b.*) the star will be at the same altitude again in $23h\ 56m\ 4s\ 09'''$ of *mean* time. Therefore, if, after the lapse of several days, say 10, (when the star will be at the same altitude nearly $40m$ earlier in the evening,) the time per chronometer be noted,

Digitized by Google

when the star comes to the alt. left on the sextant, the rate of the chronometer during the interval may be established thus:

Rule. § *d.* Multiply $3m\ 55s\ 91'''$ by 10 (days) for the acceleration (§ 213.) of sidereal upon *mean* time during the interval. Subtract the product from the time per chronometer at the first observation, and the remainder will be the time that the chronometer would have shown at the second observation, had it kept mean time *exactly* during the interval. The difference therefore between this and the chronometer time at the second obs. divided by 10 (days), will give the daily rate of the chronometer.

EXAMPLE.

§ *e.* With the sextant clamped at 60°, Altair being west of the meridian, was on the altitude of 60° with an artificial horizon, at $6h\ 10m\ 2s$ per chronometer Nov. 9th, and at $5h\ 31m\ 03s$ Nov. 19th, 1844. The interval is 10 days—

$3m\ 55s\ 91'''$ (§ 213.)
10

$39m\ 19s\ 10''' - 6h\ 10m\ 2s = 5h\ 30m\ 42s\ 90'''$

$5h\ 31m\ 3s$ Nov. 19.

$10)20s\ 10'''$ gained by chro.

$2s\ 01'''$ daily gain.

§ *f.* This method only determines the rate. Both rate and error may be found by equal alts. east and west of the meridian.

§ *g.* In taking equal altitudes of the sun, the sextant should remain clamped, and the time of contact of each limb, as well as the coincidence of the centre or images noted. But whether this method be used, or the sextant be set at different alts. and the time of each alt. noted, it is evident that the sun will be nearest the meridian at the last alt. in the forenoon, and at the first alt. in the afternoon; therefore the first A. M. and the last P. M. alt. will be the *corresponding* altitudes.

EQUAL ALTITUDES WHEN THE STAR IS ON OPPOSITE SIDES OF THE MERIDIAN.

§ 398. Let the altitude be taken, and the sextant clamped as before, when the star is east of the meridian and near the prime vertical, noting the time. Note the time also when the star comes to the same altitude, west. At half the interval the star was on the meridian; and half the elapsed time expresses its horary angle at either altitude.

§ *a.* The Nautical Almanac (pp. 448–481) gives the right ascension of the star and the sid. time (p. II.) at *mean* noon. The diff., therefore, between the times of these two transits—first correcting that for noon in the Nautical Almanac (§ 389. § *a.*) for longitude—being converted by Table XV. into mean time, will give the mean time of the transit, as deduced from observation, and consequently the error of the chronometer.

Digitized by Google

EXAMPLES.

§ *a.* January 1, 1845, long. 75° W. Sirius was at equal alts. per chro. the same evening, at 9*h* 10*m* P. M. and at 2*h* 38*m* A. M., or 14*h* 38*m*.

§ *b.* 75° = 5*h*. And (Table XIV.) the acceleration for 5*h* = 49*s* 28‴, which (§ 389. § *a.*) is therefore to be added to the sid. time at mean noon in the almanac, for the sid. time at mean noon in long. 75° W.

Sid. time	Jan. 1, (N. A. p. II.)			18*h*	43*m*	58*s*	86‴
Acceleration	do. for 5*h*					49.	28
Sid. time at mean noon in 75° =				18.	44.	48.	14
R. A. Sirius (p. 456, N. A.)				6.	38.	21.	52
Diff. (§ 389, § *e.*) =				11.	53.	33.	38
(Table XV.)	11*h*	-	-	-	= 10	58	11 87‴
	52*m*	-	-	-		52	51 31
	32*s*	-	-	-			31 91
	38‴	-	-	-			38
Mean time trans. Sirius =				11*h*	51*m*	35*s*	47‴
Time pr. chro. (half the interval)				11	54		
Chronometer fast =				+ 2*m*	24*s*	53‴	

This observation, or a similar one repeated after an interval of several days either upon the same or another star, will show what the chronometer may have gained or lost in the mean time.

§ *c.* Though equal altitudes by the stars offer advantages to the navigator, he will always prefer equal alts. by the sun; for with a star he can get but one comparison each time without moving his index, whereas with the sun he can get two comparisons, viz., one for each limb; and he may, with practice, get a third, as when the two images are coincident.

§ *d.* But the sun's declination is continually changing, and therefore the sun will come to the P. M. altitude nearer to or farther from the meridian, according as the sun is receding from or approaching the observer's parallel of latitude.

§ *e.* *Half* this difference in the horary angles is called the "Equation of Equal Altitudes," and will be readily understood after a little explanation.

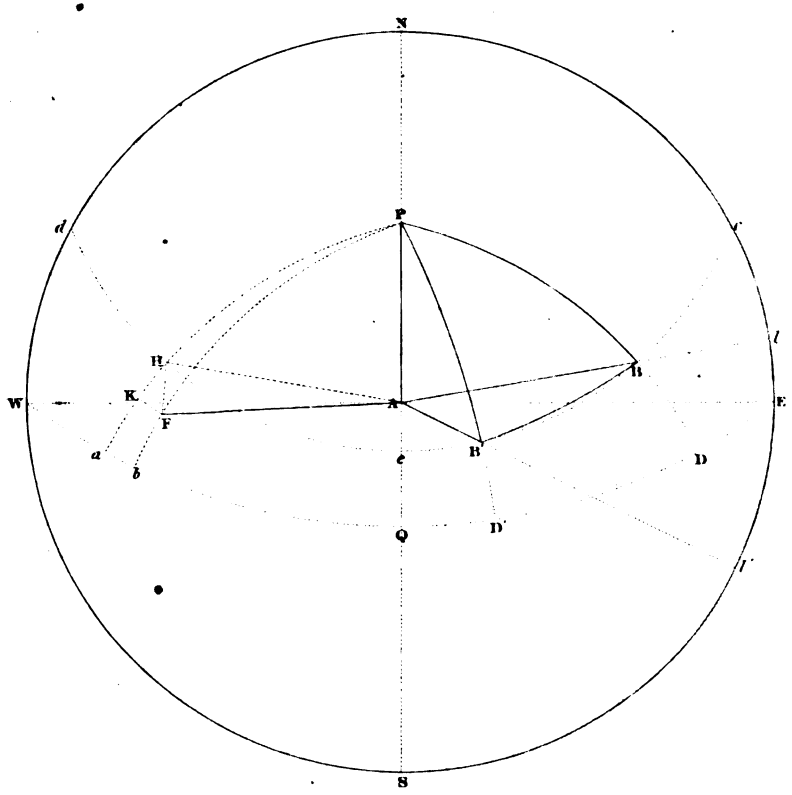
EQUATION OF EQUAL ALTITUDES.

§ 399. Let A B represent the zenith distance of the sun at the A. M. alts., and A F the zenith distance at the P. M. alts. Had there been no change of declination between the observation, H would have been the place of the sun, and A H

Plate IV.

Digitized by Google

Digitized by Google



Digitized by Google

its zenith distance at the second observation. Then the two horary angles B P A and H P A being equal, half the time between the observations being added to the time of the first, (§ 398.) would show the time per chro. of *apparent* noon.

§ *a*. But the declination of the sun is a variable quantity; suppose, therefore, the sun in dec. to be receding from the observer, it will come to the alt. on the sextant before it gets as far to the west of the meridian as it was to the east when the first alts. were taken; and therefore the horary angle A P F will be less than A P B.

§ *b*. H P F represents the difference of these two angles, half of which diff. (§ 77. § *h*.) added to half the elapsed time, will give the greater angle A P B, or the time per chro. at *apparent* noon: the arc *a b* of the equator (§ 253. and § 248. § *b*.) measures this angle H P F. } *The Diagram.*

§ *c*. A B, A F and A H are all equal, because they are zenith distances of equal altitudes; F H, therefore, represents part of an almacanther (§ 242.) or circle of equal altitudes, and H K part of a parallel of declination. Now, as all meridians cut the equator, and all vertical circles cut (§ 278. § *a*.) the horizon, at right angles, and as parallels of declination are parallel to the equator, and almacanthers to the horizon, P F K and A F H are right angles. H F P is common to the two triangles, and if it be taken from each, the remainders H F K and P F A are equal.

DEMONSTRATION.

§ *d*. The sides of the triangle H F K being necessarily very small, they may therefore for our present purposes, be considered as right lines, and the triangle as a plane triangle right angled at K. Wherefore (§ 98. § *h*.) F K = K H cot. P F A, for (§ *c*.) P F A = H F K.

§ *e*. Now, (§ 130. § *b*.) $a\,b = \frac{\text{F K}}{\text{sin. P F}}$. Substituting therefore, for F K in this equation, its equivalent as developed in § *d*., we have $a\,b = \frac{\text{K H cot. P F A}}{\text{sin. P F}}$.

§ *f*. And if we take K H for seconds of *arc*, we shall have, in seconds of *time*, $\frac{a\,b}{2} = \frac{\text{K H cot. P F A}}{30 \text{ sin. P F}}$.

§ *g*. Moreover (§ 105.) cot. P F A = $\frac{\text{cot. A P sin. P F} - \text{cos. P F A cos. P F}}{\text{sin. P F A}}$. Now A P is the co-lat. and P F the P. dist.; and if we put *d* for the change of dec. from the preceding to the following noon, to be called (§ 400. § *e*.) the *dec. change*, and *t* for the time from one observation to the other, to be called hereafter the *elapsed time*, we shall have from this and the preceding:

§ *h*. $\frac{a\,b}{2} = \frac{d\,t \text{ tang. lat.}}{1440 \text{ sin. P F A}} - \frac{d\,t \text{ tang. dec.}}{1440 \text{ tang. P F A}}$.

Digitized by Google

§ *i.* In Table XII. log. A = log. $\frac{t}{1440 \text{ sin. P F A}}$, and log. B = log. $\frac{t}{1440 \text{ tang. P F A}}$. Whence the

RULE.

Table XII. { § 400. With the elapsed time between the *corresponding* altitudes (§ 397. § *g.*) enter Table XII. and take out logs. A and B. To log. A add cot. lat. and the proportional log. of the dec. *change* for prop. log. *a*.

§ *a.* To log. B add proportional log. of dec. *change*, and cot. declination for proportional log. *b*.

§ *b.* *Dec. change* is the *change* of declination for the nearest 48 hours, *i. e.*, for the 24 hours preceding and the 24 hours after, the middle time between the observations.

§ *c.* The two values, *a* and *b*, make the equation (§ 398. § *e.*) of equal altitudes, and are to be applied according to the precepts, § *d.* and § *e.* to the approximate noon per chro. or watch; which approx. noon is found by taking the mean of the times of observation, taking care to make the P. M. hours, 13*h*, 14*h*, 15*h*, etc., instead of 1, 2, 3, etc. Thus, suppose the times of the P. M. observation to be 2*h* 9*m* 3*s* and 2*h* 13*m* 40*s*, they should be recorded 14*h* 9*m* 3*s* and 14*h* 13*m* 40*s*.

§ *d.* Add *a* when the P. distance *increases;* and subtract *a* when the P. dist. *decreases*.

§ *e.* Subtract *b* when the sun approaches the equator; and add *b* when the sun recedes from the equator: *i. e.*, *b* is addative from the equinox in March till the solstice in June, and from the equinox in Sept. till the solstice in Dec. The rest of the year *b* is *subtractive*.

EXAMPLE.

§ 401. Nov. 15th, 1844, lat. 38° 54′ N., long. 77° 4′ W. J. L. Worden, U. S. N., having his sextant clamped at 46° 16′ 50″, found the times per chronometer, A. M. and P. M., when the limbs of the sun passed their alts. through the art. horizon, to be

Plate 3. § 404. By inspecting the triangle (P B A) of the problem for finding the apparent time of day, it becomes evident, that if, of the lat., time of day, dec., alt., and azimuth, of the sun, or any other body, any three be known, the two others are determinable.

§ *a.* The azimuth gives the angle P A B; and the apparent time of day gives the angle A P B; the altitude (B *l*) determines the zenith distance A B; the latitude A Q, determines P A, the co-lat., and the declination k B, determines the polar distance P B.

TREATMENT OF CHRONOMETERS.

§ 405. Chronometers that have been rated on shore, generally change their rate more or less when put on board ships, particularly on board vessels of war. Therefore in a man-of-war, it is desirable to have the chronometers on board at least two or three weeks before sailing, and to rate them on board by means of equal altitudes from the artificial horizon. If equal altitudes cannot be had, then forenoon sights *altogether*, or afternoon sights altogether, (the former are the best,) should be used.

The sea horizon should never be used for rating chronometers.

As soon as the chronometers are received on board, they should be put in the places intended for them, and there they should remain. The comparing watch is intended as a *hack* chronometer, to be taken on deck, and on shore when necessary, for taking time by. But it should always be compared with the chronometer immediately before and after the observation.

Whether chronometers be rated by means of the sun or stars, that time should be chosen for making the observation, when the change of altitude is most rapid. This generally occurs when the bearing of the sun or star is about east or west. Alts. lower than 8° or 10° are not to be relied upon on account of uncertain refraction.

Chronometers for the Navy are taken on trial for a year at the Depot of Charts, Washington City, where they are daily compared and their rates ascertained. At the expiration of their trial term, the "mean of their monthly extreme variations is added to twice the diff. between the extremes in the monthly columns of mean" daily rates; if this sum exceed 8*s*, the chronometer is rejected. It is only within recent years that chronometers could stand such a severe test. In 1828 the English Admiralty offered rewards for the best chronometer. 80 were put on trial for the premium, and the trial No. of the best was, by this rule, 16*s*. Such a chronometer now would not be purchased.

LATITUDE BY MERIDIAN ALTITUDES.

§ 406. The most common and convenient method of determining latitude at sea, is by means of an altitude of a celestial body, measured when that body is on the meridian.

§ *a*. Then the circle of the body's declination coincides with the meridian (N A S) of the observer.

§ *b*. Suppose the body be a star; the zenith distance (A *e'*) (§ 282. § *b*.) expresses the number of degrees, etc., from (A) the zenith to the star. } Plate 3.

§ *c*. And the declination Q *e'* (§ 255. § *b*.) gives in the same measure, the distance of the star from the equator.

§ *d*. Wherefore the declination (Q *e'*) *plus*, the zenith distance (A *e'*) gives A Q the latitude.

§ *e*. The sun being south of the observer, and its declination 10° 20′ south, its meridian altitude (corrected) was 59° 40′.

Digitized by Google

To find the latitude of the observer,

§ *f*. The sun's altitude (§ 282. § *a*.) is *e* S; 90°—*e* S=A *e* (§ 282. § *b*.) the zenith distance.

§ *g*. The observer being at A, north of the sun, makes (§ 281. § *b*.) the zenith dist., A *e*, *north*.

§ *h*. The dec. Q *e*, being taken from the zenith dist. A. *e*, leaves A Q the required latitude.

Plate 3.

§ *i*. Sun's Z. D. (§ *a*.) = 30° 20′ N. (§ *b*.)
Sun's dec. = 10° 20′ S.

Lat. = 20° 00′ N.

§ 407. Suppose the star to bear south, but its dec. to be 9° 3′ N. and its meridian alt. 79° 3′.

To find the latitude,

§ *a*. The star's alt. is *e*′ S; A S—*e*′ S = A *e*′ the *'s zenith dist.

§ *b*. The dec. Q *e*′ being added to *e*′ A the zenith dist., makes A Q, which is the latitude.

§ *c*. *'s Z. D. = 10° 57′ N.
*'s dec. = 9° 3′ N.

Lat. = 20° 00′ N.

§ *d*. Suppose the star to be north of the observer, its declination 60° 5′ N., and its meridian alt. = 49° 55′.

To find the lat. of the observer,

§ *e*. N *e*″ is the *'s alt. The zenith dist. (§ 281. § *c*.) is south; N A—N *e*″ = A *e*″, the *'s zenith dist.

The dec. Q *e*″—A *e*″ (the zenith dist.), gives A Q, the lat.

*'s dec. = 60° 5′ N.
*'s Z. D. = 40° 5′ S.

Lat. = 20° 0′ N.

§ 408. Wherefore, when the dec., and the meridian zenith dist., are both north, or both south, their *sum* is the latitude.

§ *a*. And, when one is north, and the other south, their *difference* is the latitude.

§ *b*. When the body is in the zenith, there is no zenith dist., and the dec. is the lat.

Rules.

CIRCUM-MERIDIAN ALTITUDES.

§ 409. It often occurs that the sun is obscured just at the meridian, so its altitude cannot be taken then, though it may be a few moments afterwards, or might have been a short time before. In such cases the latitude may be determined almost as readily and quite as accurately as by a meridian observation.

§ *a*. Altitudes taken near the meridian are called circum-meridian altitudes, and there are two methods of computing lat. therefrom: one is when the alts. are taken all on one side of the meridian: the other when they are taken on both sides.

Digitized by Google

§ *b.* It is readily understood how the sun's motion in altitude is least near the meridian; and that, except when nearly in the zenith, a circum-meridian altitude should vary, mile for mile, with the lat., almost as regularly as a meridian alt.; and also, when the difference between the lat. and dec. is considerable, that the *difference* between the circum-meridional and meridional altitudes, remains nearly the same for the same hour angle, at parallels separated a degree or more in lat. This "*difference*" is called the *Reduction to the Meridian.*

§ *c.* If, therefore, at the time of taking a circum-meridional altitude, the sun's hour angle, or the *apparent* time of day, be known (even approximately), the latitude may be determined with considerable accuracy. If the hour angle A P B were accurately known, the other given parts would be the zenith distance A B, and the P. dist. P B; from which A P, the co-lat., might be determined by Case 1, (§ 197. § *o.* and § *p.*) Oblique Spherics. Plate 4.

But at sea, this angle cannot be given accurately: it may, however, be obtained approximately by the chronometer, by applying its error, and then allowing for longitude and the equation of time, (§ 283.) in order to get *apparent* time at ship. If a watch be used, its error on apparent time should be determined at the first opportunity, allowance being made for the change of longitude in the mean time. *Reduction to the Meridian.*

§ *d.* Having by this means, the approximate *apparent* time at ship when the alts. were taken, if we put l for co-lat., P for P. dist., H for approximate hour angle, Z for meridian zenith dist., (*computed*), and r for the reduction, we shall have, (§ 181. § *g.*),

Cos. $H = \frac{\text{cos. } (Z + r) - \text{cos. } l \text{ cos. P}}{\text{sin. } l \text{ sin. P}}$; and consequently, 2 sin.^{2} $\frac{H}{2} = \frac{\text{cos. } (l \sim p) - \text{cos. } (Z + r)}{\text{sin. } l \text{ sin. P}}$. But $l \sim P = Z$. Wherefore, by reduction, 2 sin.^{2} $\frac{H}{2} = \frac{\text{sin. Z sin. } r}{\text{sin. } l \text{ sin. P}}$ nearly. Hence sin. r = 2 sin. l sin. P co-sec. Z sin.^{2} $\frac{H}{2}$; or r, in seconds of space, $= \frac{2}{\text{sin. } 1''}$ cos. lat. cos. dec. co-sec. Z sin.^{2} $\frac{H}{2}$. And the log. of $\frac{2}{\text{sin. } 1''}$ is 5.615455; which is a constant quantity: Whence the rule:

§ 410. To the constant log. 5.615455 add *twice* the sine of $\frac{1}{2}$ the *approximate hour angle* (§ *a.*), plus co-sec. *computed* (§ 411. § *a.*) meridian Z. dist., *plus* cos. dec., *plus* cos. lat. by account:—The sum of these, rejecting the tens from the index, is the log. of the seconds (″) to be subtracted from the *observed* zenith distance, (corrected for semi-diameter, dip, refraction, etc.); this gives the *true* meridian zenith distance. *Rule.*

§ *a.* When the sun is used, the *approximate* hour angle is the *diff.* between the *assumed* time and 12*h*, or noon (*apparent time*).

§ *b.* When a star or planet is used, subtract its R. A. from ⊙'s

Digitized by Google

R. A., *plus* the *approx. app.* time: the remainder is the *approx.* hour angle (§ *a.*)

§ 411. Nov. 19, 1844, long. 74° W., lat. by act. 39° N., ☉'s alt. at sea was 31° 13′, and time per chro. 16*h* 40*m* 36*s*. Required the reduction to the merid. and the lat.?

If the lat. by act. be much out, the operation should be repeated, taking the lat. found by the first, as the lat. by act. in the second, operation.

On both sides of the meridian.

§ 412. When the time is accurately known, circum-meridian altitudes on *both* sides of the meridian, offer the most accurate means ordinarily within the navigator's reach, of determining the lat., except meridian altitudes of north and south stars, taken from an artificial horizon, when they are on the meridian.

§ *a.* The method of deducing lat. from circum-meridional altitudes is founded on the principles just explained, and with the view of facilitating the practical navigator in the solution of this highly important and useful problem, Table XVI. has been calculated, which very much simplifies the process, and

Table XVI.

Digitized by Google

gives the result sufficiently near for all practical purposes of lat. at *sea*. The *extremes* of error by this table may sometimes amount to a minute or two; but in most cases, the result is as accurate as the altitude can be taken, by the ordinary means, from the sea horizon.

§ *b*. Table XVII. is added to show the hour angles *within* which the alts. should be taken under different decs. and lats. } Table XVII.

§ *c*. The alts. should be taken about the same distance on each side of the meridian, that the reductions may compensate for any small error of hour angles. The nearer the meridian the more accurate the results. } *Taking the Altitudes.*

§ *d*. The stars and planets may be used, as well as the sun, in this observation. Indeed, the North star, from its slow motion, is peculiarly favourable for it. But when a star is used, its hour angle must be found as under § 388.

§ 413. Take from Table XVI. the *reduction* for the app. time at each alt., and take the mean of these *reductions*. Then to the log. of this mean, add cos. lat. by account, cos. dec. and co-sec. merid. Z. dist. (computed if necessary): the sum of these four logs. is the log. of a correction *in seconds* (″) to be subtracted from the mean Z. dist. } *Rule.*

§ *a*. At midnight this correction is addative.

EXAMPLE.

§ *b*. Nov. 27, 1844, in lat. by account, 38° 50′ N., the following circum-meridian altitudes (corrected for semi-diameter, refraction, etc.) were observed.

§ *c*.

LATITUDE BY DOUBLE ALTITUDES.

§ 414. The sun, (and every other celestial object,) is frequently obscured by clouds, so that neither a meridian nor a *circum-meridian* alt. can be measured.

§ *a.* Under such circumstances, data sufficient for determining the lat. may still be obtained by taking at two different hours of the day and at any hour angle, the sun's alt., and noting the time that elapses between the two observations.

§ *b.* This *elapsed* time, expressed in degrees, or hours, etc. (§ 348. § *b.*), constitutes, with the zenith and polar distances, sufficient data for finding the latitude.

§ *c.* This method of finding the latitude is called "by *Double Altitudes.*"

§ *d.* The process of calculation is tedious, but the result will give the latitude with sufficient correctness for all the ordinary purposes of navigation. It is therefore useful and important

Plate 4. § 415. *For determining the lat. by "double altitudes."* B D represents the declination, and B *l* the alt. of the sun, at the first observation; and B′ D′, and B′ *l′* the dec. and alt., at the second observation.

§ *a.* A P B is the sun's horary angle at the first, and A P B′ its horary angle at the second, observation.

§ *b.* The difference (B′ P B) between these two angles, is the angular value of the time (§ 414. § *b.*) that elapses between the observations.

§ *c.* B B′ is the arc of the great circle, which passes through the points, in which the centre of the sun was at each observation.

§ *d.* The other circles, arcs and angles, of the Fig., are explained under § 317. (§ *a.*)

The diagram. § *e.* The problem of "double altitudes" involves three triangles (B′ P B, A B B′, and A P B′) in the process of solution.

§ *f.* The side B′ B is common to the first and second triangles; P B′ to the first and third, and A B′ to the second and third.

Digitized by Google

§ 416. The parts that are given in the first triangle (B′ P B), are the two sides, P B and P B′ (§ 415.), which are the P. dist. (§ 258.) at the first and the second observations; and (§ 415. § *b*.) their contained angle B′ P B = Elapsed time. (§ 414. § *b*.)

§ *a*. And the parts required are, the third side B′ B, and the angle P B′ B.

§ 417. The value of P B′ B and B′ B being determined by calculation, the parts that are then known in the second triangle A B B′, are B A and B′ A (§ 415.) (which are the zenith distances (§ 281.) of the sun at the first and the second observation) and the common side B′ B.

§ *a*. The part here required, is the angle A B′ B.

§ *b*. The difference between the angles A B′ B, and P B′ B (§ 416. § *a*.) gives the value of the angle A B′ P, in the third triangle A P B′.

§ *c*. Then in the third triangle, the two sides A B′, P B′, and their contained angle A B′ P, are the given parts; and P A is the part required, and the co-lat.

§ 418. In north latitude, at 7 A. M. by a watch:

Sun's true alt. 24° 58′ 12″
Sun's dec. 22° 25′ 00″ N.

§ *a*. And at the 10*h* 15*m* by the same watch.

Sun's true alt. 62° 49′ 20″
Sun's dec. 22° 24′ 00″ N.

Solution.

Correcting for the distance sailed.

§ 421. In the example last quoted, the two observations are taken at the same place; but in practice, this cannot always be done, especially at sea, when the vessel is changing her place during the time that elapses between the taking of the observations.

§ *a*. Therefore the 1st altitude must be corrected, in order to know what it would have been, had it been taken at the same time per watch, but at the place where the 2d obs. was made.

§ 422. When the first observation is being made, note the bearing of the sun and the course of the ship; and after the second observation has been taken, find in a traverse table (Table IV.), the course and distance from the place where the first, to that where the second, observation was taken.

§ *a*. The angle, which this distance makes with the bearing of the sun, being used in the traverse table, as a course, the correction which is to be applied to the first alt., is found under this course, and opposite to said distance, and in the column marked "d. lat."

§ 423. If this angle be less than 90°, the correction thus found is addative.

§ 424. If it be greater than 90°, its supplement is the course; and,

§ *a*. The correction is subtractive.

§ 425. If the ship sail on the line of the sun's bearing, the distance sailed in miles, is the correction in minutes (') of a degree.

§ *a*. It is addative when the ship sails towards the sun; and,

§ *b*. Subtractive when she sails from the sun.

§ 426. The corrections are found as nautical miles, but are to be applied to the altitude as minutes (') of a degree.

§ 427. When the angle between the bearing of the sun, and the course which the ship makes, is 90°, there is no correction.

§ 428. The corrections thus obtained and applied, do not show *exactly* what the 1st altitude would have been at the place of the second observation; but the approximation is sufficiently close to answer the purposes of common navigation.

§ 429. The time that elapses between the taking of the observations, should not be less than 30*m*, or more than 6*h*, if avoidable, especially if the observer be at sea.

§ *a*. If the body under observation do not change much in declination during the "elapsed time," the *mean* of its declination at the two observations may be used as the body's declination at each observation.

§ *b*. This "*mean*" declination is found by taking out the declination for half of the "elapsed time," and applying it to the time of the first observation.

§ *c*. When the *mean* declination is used, P B = P B'; and the first triangle B' P B (§ 140.) is isosceles. } Plate 4.

§ 430. The latitude at the time and place of the first observation, may be found, if required, by making A P B the third triangle, and using the angles P B B', A B B' and A B P, instead of P B' B, A B' B and A B' P (§ 420. § *b*. and § *c*.).

§ *a*. But generally, in navigation, the latitude at the time *present*, is most desirable to be known; and usually, when the problem is solved,

Digitized by Google

the vessel is nearer to the place of the second, than she is to the place of the first observation.

§ *b. A formula for practice in finding the latitude at sea by "double altitudes;" the mean declination being used. Vide* § 418.

§ *d.* The result by this method differs somewhat from the truth. Like every other trigonometrical calculation, in which *true* data are not operated upon, it brings an error into the result; but the result is an approximation, which oscillates about the truth, and within limits that depend upon the correctness of the assumed data.

§ *e.* Some navigators solve the problem of "double altitudes" by the method proposed by a Mr. Douwes; but the correctness of the result, by his method, depends upon repeated calculations, or the proximity of a *supposed*, to the correct, latitude."*

§ 431. Latitude by "double altitudes" may also be determined by taking, at the same instant, the altitudes of any two bodies, whose right ascension and declination are given.

§ 432. The method of solving this problem consists in a process of operation precisely similar to that (§ 420.) for finding the latitude by means of two altitudes of the same body, taken at different times.

§ 433. The difference in right ascension of the two bodies gives an angle, which corresponds to the angular value (B′ P B) of the "elapsed time," between the two observations. Plate 4.

* Mr. Douwes's method is both supported and questioned by high authority. Bowditch has adopted it in his PRACTICAL NAVIGATOR. And there is a paper from M. Delambre, showing that the result by this method is not always an approximation, but that, in some cases, if repetitions be made, the result will differ more and more widely from the true latitude.

Digitized by Google

By two planets at the same time.

§ 434. When the difference in right ascension of the two bodies exceeds 180° or 12*h*, the greater right ascension, subtracted from the less *plus* 24*h*, gives the angle corresponding to B′ P B.

§ 435. In this method of finding latitude, the altitude of the moon, unless the Greenwich time be known, cannot be used with certainty of success. For the moon's variation in declination and right ascension is so rapid, that unless the Greenwich time of day, when the observations are made, be known, the proper value of the angle corresponding to B′ P B cannot be obtained.

§ 436. The stars afford the greatest facilities for the practical application of this problem.

§ *a*. Their variation in declination and right ascension being, for the most part, not very rapid; consequently when the horizon is well defined, the data requisite to the solution of the problem can be obtained by means of the stars, with sufficient accuracy.

EXAMPLES.

§ 437. In north lat. June 2, 1834, Jupiter being east, and Mars west of the meridian; their altitudes were taken at the same instant;

J.'s alt.	71°	49′		To find the latitude.
" dec.	18°	0′	40″ N.	
" R. A.	3*h*	27*m*	36*s*

tutes the angle which is contained between the P. Distances of the two bodies; and with the polar and zenith distances of these bodies, it also constitutes the required data of the problem.

§ 448. The sum or difference of the *difference* of the two bodies in right ascension, and the portion of *mean time* from one observation to the other, give the required contained angle.

§ *a*. If the sun be the second object, the *apparent* instead of the *mean* time, from one observation to the other, must be taken.

Illustration.

§ 449. The sum of said two quantities is the value of this angle, when the first object is to the eastward of the second.

§ 450. But when the second is the more eastwardly object, the difference of the two in right ascension, *minus* the *elapsed* time, gives the value of the required polar angle.

451. If, when the second is the eastern object, the elapsed time exceed the difference in right ascension of the two bodies, the second will have crossed the hour circle (§ 263. § *c*.) which coincides with the circle of declination, in which the first object was when its altitude was measured.

§ 452. The excess of the elapsed time above this difference in ascension, is the value of the required polar angle (B′ P B).

Plate 6.

§ 453. B represents the place of Venus (the first object), when its altitude was taken.

§ *a*. Venus was then the morning star, and, consequently, to the westward of the sun, (which is the second object).

§ *b*. Venus' altitude was taken in the morning, when the sun was below the horizon.

§ *c*. P *b* is an arc of the circle of right ascension in which the sun was, when Venus' altitude was taken.

§ *d*. B P *b*, is the angular value of the difference in right ascension of the sun and Venus, when the altitude (B *l*) of the latter was taken; it is about 2*h* 36*m* 54*s*.

Plate 6.

§ 454. The sun's altitude B′ *l*′, was taken 4*h* 29*m* 45*s* after Venus' was measured.

§ *a*. The sun had then crossed over the hour circle P B (§ 263. § *c*.) in which Venus was, when its altitude was taken.

§ *b*. The sun was at B′, to the west of this circle, when its altitude was taken.

§ 455. B′ P *b*, is the horary angle, in *apparent* time, which the sun described during the interval between the taking of the altitudes.

§ *a*. Consequently the difference (B P *b*) of the sun and Venus in right ascension, when their altitudes were measured, subtracted from (B′ P *b*) the angular value of the *apparent* time between the observations, gives the value of the angle B′ P B.

§ *b*. If the portion of time that elapses, between the observations, be given in mean time, it may be converted into apparent time, by applying to it the fraction which during the elapsed time, the second object's equation of time gains or loses, on mean time.

§ *c*. In surveying expeditions the elapsed time should be corrected

Digitized by Google

and changed into *apparent* time, in order to determine the latitude with exactness.

§ *d.* But upon the open sea, this nicety in operation may be omitted, for it only advances, by a very small fraction, the accuracy of the result.

§ *e.* If the altitude of the more easterly object be taken last, and the elapsed time be equal to their difference in right ascension, the same hour circle (§ 263. § *c.*) will pass through each object when its altitude is taken; and the process of deducing the latitude will be confined to the simple operation of finding an angle with the three sides of a triangle as data; and thence in deducing, from the two sides and their contained angle, as data in a second triangle, the value of its third side, which is the co-lat.

§ *f.* The three sides of the former of these two triangles, would be the zenith dist. of each body, and the difference between their polar distances.

§ 456. Feb. 25, 1832. Venus being the morning star, and the observer being in south latitude when he made his observations:

§ *a.* Venus' Alt. 24° 50′ (*True.*)
" Dec. 20° 5′ S.
" Rt. Ascen. 19*h* 59*m*
" bearing E. ¼ S. (§ 443. § *a.*)
Time per watch 3*h* 16*m* 19*s*

§ *b.* The ship then sailed N. E. ¼ N. 18 miles, when the sun was seen, and its altitude taken.

Sun's Alt. 43° 44′ (*Correct.* § 385. § *b.*)
" Dec. 9° 16′ S.
" Rt. A. 22*h* 30*m* 59*s*
Time per watch 7*h* 46*m* 8*s*

§ 457. The angle between the bearing of Venus (§ 456. § *a.*), and the ship's course, is five points, which (§ 422. § *a.*) with the distance sailed, (18 miles), gives 10′ (§ 426.) in the column (*d. lat.*) of the traverse tables; which 10′ (§ 423.) being added to Venus' altitude, makes it 25°, (what it was at the time of its being taken, but at the place where the sun's alt. was observed.)

§ *a.* The watch kept *mean* time. The elapsed time (§ 455. § *b.*) must therefore be corrected, in order to obtain the portion of *apparent* time, that elapsed from the first, until the second observation was taken.

§ *b.* During this interval there were 2*s* *less* of apparent than of mean time which being subtracted from the mean time elapsed, gives the elapsed apparent time.

§ *c.* This correction is obtained from the ephemeris. It is the quantity which the equation of time gains or loses from the first to the second observation; and it must be applied accordingly.

Plate 6. § *d.* The triangulation, through which the process of finding the latitude by means of the data in this problem is conducted, is represented in the triangles B′ P B, A B′ B and A B′ P.

SUMNER'S METHOD.

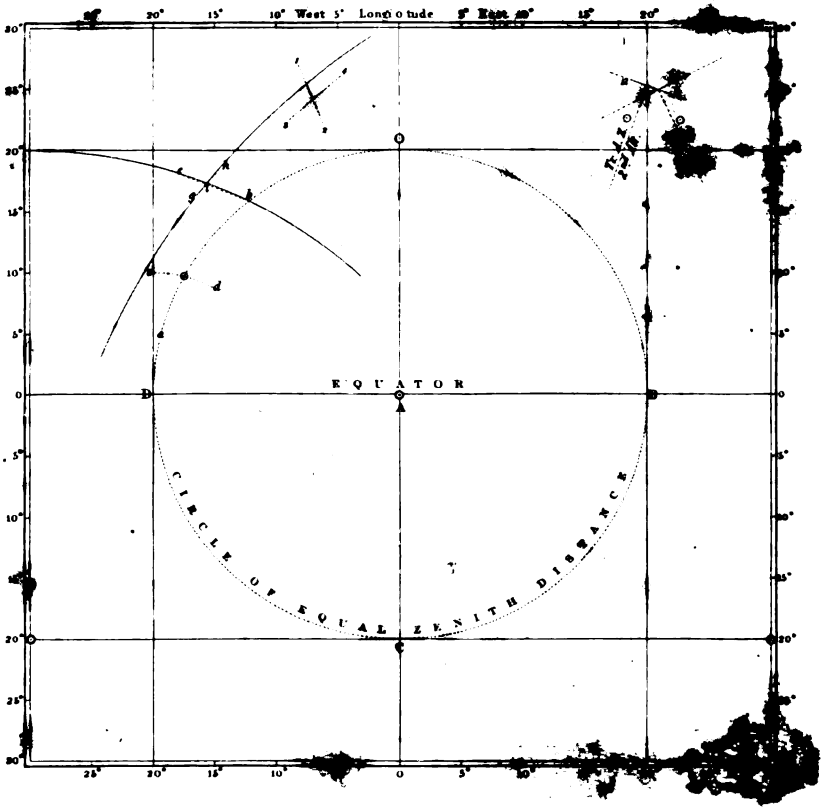
§ 459. Capt. Sumner, of Boston, has proposed a method for finding —partly by calculation, partly by projection on Mercator's chart—both latitude and longitude, by "Double Altitudes."

§ *a.* The only calculation required by this method is the ordinary one (§ 387.) for finding apparent time, which, being repeated four times, gives both long., per chro. and latitude.

* This differs 1″ from the truth.

Digitized by Google

Digitized by Google



Digitized by Google

§ *b*. In order to find the time, the lat. is assumed in each of these four calculations; but if the chronometer be correct, the result differs from the truth by a very small quantity; which quantity is the diff. on the charts between the point of intersection of two small arcs and of their chords.

§ *c*. This is a valuable method; and, considering the degree of perfection to which chronometers have been brought, it bids fair to become a favourite one with practical navigators, whenever it is *necessary* for them to resort to "Double Altitudes" at all other than circum-meridian alts.

§ 460. Suppose any object, say the sun, to be on the equator, and on the meridian of Greenwich at the same time. Suppose also that there be four observers, two on the meridian and two on the equator, as at O and C, D and B; that O be in 20° N., C in 20° S., B in 20° E., and D in 20° W. Each is therefore 20° distant from the point of intersection of these two great circles; and if, the instant the sun is at A, they all should observe its altitude, its true zenith distance from each would be 20°. } *Illustration.* } Plate 7.

§ *a*. Now, if from the scale of any chart we take, with a pair of dividers, the distance of 20°, and with one foot on A, describe an elipse, as O B C D, we shall have a circle of equal zenith distance, from any part of which either of the observers would have had the same alt., and therefore the same Z. dist. The same remarks would apply to the sun and stars at any other altitude and declination.

§ *b*. (The circles of equal Z. distances appear on Mercator's chart as elliptical figures, more or less elongated according as they are described with a greater Z. dist. and over degrees of higher latitude. The diagram here is supposed to include each side of the equator, because, near the equator, the diff. in length between a degree of lat. and one of long. is small, and the circle of equal zenith distance appears very nearly as a complete circle; it is here so considered, and as such answers all the purposes of illustration.)

§ *c*. Now suppose there had been an observer at some intermediate point between D and O, whose chro. was correct, but whose latitude was unknown. He first supposes himself to be in lat. 5°; in which case with the Z. dist. of 20°, the latitude of 5° and dec. 0°, his chro. (§ 402.) puts him in long. as at *a*, where this circle crosses the parallel of 5°.

§ *d*. He again supposes his lat. to be 15°, and again works out for longitude by chro. with the same dec. and Z. dist. By this second operation his chro. puts him at *b*, where this circle of equal Z. dist. crosses the parallel of 15°.

§ *e*. It rarely happens that a navigator is 10° or 5°, or even 2° of lat. out of his reckoning. Let us, however, suppose that he is somewhere between the parallels of 5° and 15°: he is on the arc between *a* and *b*, because his chronometer is right, and showed the sun to be at A, on the meridian of Greenwich, when the alt. was taken. The time at Greenwich was *apparent* noon.

§ *f*. Now if we could get the altitude of an object in another part of the heavens, we should have another zenith dist. circle, upon the circumference of which, also, the observer would be. The point, there-

Digitized by Google

fore, at which these two circles intersect each other would be the place of the observer.

§ *g*. Let us therefore suppose that he waits 1*h* 20*m* (= 20° long.) (§ 346. § *a*.) when he takes another alt. of the sun. His chronometer shows that the sun has passed the meridian of Greenwich 1*h* 20*m*, (supposing the dec. to be the same) and that therefore the sun is at D on the meridian of 20° west. Suppose the alt. to be 80°; *c d* therefore is part of the zenith distance circle, and *o* (§ *f*.) the place of the observer, in lat. 10° N., long. 17° 40′ W.

§ *h*. But zenith dist. circles (§ *b*.) being elliptical, cannot be drawn on a chart without great trouble. Therefore, if, instead of projecting a circle as in the diagram, we had have supposed the observer in the first instance to be in lat. 5°; and then if, with the zenith dist. of 20° and dec. 0, we had calculated the long. per chronometer, it would have put us at *a*.

§ *i*. If again, with the same Z. D. and dec. we had taken the lat. of 15°, and made a similar calculation, this last would have put us, by chronometer, at *b*.

§ *j*. A straight line therefore from *a* to *b*, when the two assumed lats. do not differ more than 1° or 2°, would pass *nearly* (§ 459. § *b*.) through the observer's place.

§ *k*. If he did in like manner with the second circle of zenith distance, he would have another straight line crossing the first, and their point of intersection would be the place of the observer.

§ *l*. Thus, suppose the dec. to be 20° S., and the apparent Greenwich time 10*h* A. M. or 2*h* *before* noon, and the Z. D. to be 59°. With this dec. and Z. dist. and the assumed lat. 16° 15′ N., the place per chronometer would be at *g*. With the same Z. dist. and dec. in lat. 17° 45′, the position would be at *h*, and the observer somewhere on the line *g h*.

§ *m*. Suppose that 4 hours afterwards, or at 2 P M. *apparent* time, when the sun is at ⊙ (30° W.), the same operation to be repeated with a Z. dist. of 40°, the two positions would be *b* and *e*, and the true place *i* (*nearly*) the point of intersection of the two chords of these two arcs.

§ *n*. The *true* place is at the intersection of the arcs themselves.

§ 461. From the foregoing demonstration several valuable corollaries suggest themselves.

§ *a*. *Cor*. 1. It appears from the diagram that the more nearly the two lines *e b* and *g h* intersect at right angles, the more accurately will the position be marked; and that therefore the nearer the bearing of the object at the second observation is at right angles with its bearing at the first, the better.

§ *b*. If the diff. of bearing be not less than 45° nor more than 135°, the position of the ship may be obtained with tolerable accuracy.

Line of position.

§ 462. *Cor*. 2. The *line of position e b* is the chord to a very small arc; a perpendicular bisecting this line would pass through the centre of the zenith distance circle.

§ *a*. Therefore a perpendicular to either line of position being drawn on the chart, would show the azimuth of the sun or star at the time of observation; and if the magnetic azimuth (§ 320. § *a*.) be taken with the altitude, the variation may be determined without calculation sufficiently near to *steer* by, (*i. e*., within ½ pt.) But it is not recommended to *rely* on this method for "Variation."

Digitized by Google

§ *b*. The course which the perpendicular (§ *a*.) to the line of position, makes on the chart, is the *true* azimuth at the time of observation.

§ 463. Let us take the case of a ship that had been several days without an observation. Her lat. by account is 25° N., which may be 45′ in error, more or less.

§ *a*. On the morning of Dec. 10, 1844, an observation was had as follows:

Example.

⊙ alt.	30° 10′	Time per chro.	7*h* 40*m* 36*s*

Plate 7.

§ *e.* Now upon the parallels of 24° 15′ and 25° 45′, set off these two longitudes (§ *b.*) as before; draw the line of position *u k* between these two places on the chart; and the point of intersection of this line with the other (§ *b.*) shows the place of the ship.

§ 464. In finding position at sea by this method, time will be saved by ascertaining the first line of position by calculating the time from the first alt. as soon as it is taken. And when the second alt. is taken, reduce it (§ 457.) to what it would have been had it been taken where the first was. Nothing is gained by waiting till the second alt. be taken in order to reduce the first to its place; for in either case, the errors of the "Dead Reckoning" between the observations are retained in the result.

§ *a.* Thus, in the example above, suppose the ship had sailed from the first to the second observation, 18 miles, her course making an angle of 5 points, with the sun's bearing at the first obs., and that the second alt. had been 36° 28′ 45″. The correction (§ 457.) being *subtracted* from 36° 28′ 45″, would have given the required reduction.

§ 465. Instead of the sun at different times, the alt. of the sun and moon, of the moon and a star or planet, or of two stars, taken at the same time, may be used.

§ *a.* Where the objects are two stars, proceed to find the time, and thence the long. of both the maximum and minimum lats. as pr. § 389., and draw the lines of position to get their intersection; you have then the place of the ship without the trouble of pricking it off.

§ *f*. Which two positions being projected on the chart, give the line of position 3, 4. The point of intersection between this and 1, 2, shows the place of the ship.

§ *g*. The calculations for finding lat. and long. by this method are only those for finding time. Therefore if two stars be used, either for altitudes taken at the same time, or at different times, the navigator has only to follow the rules already given for finding time by the stars, making the reductions when necessary for change of position between the observations. For Capt. Sumner's own account of his method, see his pamphlet on the subject, published by Thos. Groom & Co., Boston.

LITTROW'S METHOD.

§ 467. The astronomer at Vienna has proposed a method for finding the latitude, by simply observing three altitudes near the meridian, (say within the limits of Table XVII.,) and noting the *elapsed* time between the observations. All that is required of the time-piece in this instance is, that it should give correctly the *interval* between the observations. Each of the three altitudes may be taken one after the other, with an interval of not more than two or three minutes, or even less.

Digitized by Google

§ *a*. By this method the calculations may be made, and the latitude may be found with or *without* the use of logarithms.

§ *b*. Call the *diff.* (*in seconds*) between the 1st and 2d alt. a
" " " " " 1st and 3d alt. a'
" " " " " 1st and 2d time t
" " " " " 1st and 3d time t'

Formula.

§ *c*. Let $m = t\ a'$; $m' = t'\ a$; and $x = \frac{m'\ t'\ \backsim\ m\ t}{2\ (m'\ \backsim\ m)}$ which is the approximate hour angle at which the first observation was made.

§ *d*. Then calling r the *reduction to the meridian* for the first alt., we have $\frac{x^2}{tt'} \times \frac{m'\ \backsim\ m}{t'\ \backsim\ t} = r$.

Depôt of Charts, Washington City.

Example.

Alts.	Time.	
⊙ 37° 16′	11*h* 48*m* 19*s*	Interval.
37. 17. 20″ diff. 80″ = a	49. 31. 5 =	72″ 5 = t
37. 19. 35 " 215 = a'	51. 41 =	202 = t'

§ *e*. $m' = (202 \times 80) = 16160$ (§ *c*.)
$m = (72.5 \times 215) = 15587.5$

§ *f*. $572.5 = m'\ \backsim\ m$
2

§ *g*. $1145.0 = 2\ (m'\ \backsim\ m)$ (§ *c*.)

$m'\ t'\ (16160 \times 202) = 3264320$ (§ *e*. and § *b*.)
$m\ t\ (15587.5 \times 72.5) = 1130093$ (§ *e*. and § *b*.)

$2134227 \div 1145$ (§ *g*.) $= 1864s = x$.

The first altitude was therefore taken at an approximate hour angle of 31*m* 4*s*, or at 11*h* 28*m* 56*s*.

To find r (§ *d*.), *or the reduction to the meridian.*

$\frac{x^2}{tt'}$ $(3474496 \div 14645) = 237.2$ (§ *d*.)

$\frac{m'\ \backsim\ m}{t'\ \backsim\ t}$ (§ *f*.) $(572.5 \div 129.5) = 4.4$

9488
9488

60)1043″.68 = r

17′.23″ = Reduction to the meridian;

which being added to the first altitude, corrected for semi-diameter, dip, refraction, etc., gives the meridian altitude due the place of observation, and consequently (the declination being known) the latitude, e. g.:

Digitized by Google

1st Alt. ⊙	37° 16′

Z. dist. - -	52. 10. 15
Declination S. -	13. 16. 35
Latitude - -	38. 53. 40

The slower the change of altitude, and consequently the nearer to the meridian when these observations are taken, the more accurate the result. The north star is particularly favourable for latitude by this method.

As simple and as convenient as this method is according to the formula and example first, it may be rendered still more simple and convenient, by taking the altitudes at equal intervals of 100*s*, 200*s*, 300*s*, according to convenience, taking care always that the alts. are *good*, and the intervals *exact*. *Try it.*

LUNARS.

§ 468. The problem of finding the *true* distance between the sun, or a star, and the moon, for the purpose of thence determining the longitude, is one of great importance in navigation.

The necessity for the circuity of calculation in finding the longitude by lunar observations, arises from the circumstance that the two observed bodies are not seen (§ 289.) in their true places.

§ *a*. They always appear, each in its proper azimuth circle, but higher up, or lower down in it (§ 283. § *c*.) than it really is.

§ *b*. And consequently (§ 283.) they appear either nearer to, or farther from, each other, than they really are; which makes the difference between the true, and apparent lunar distance.

§ 469. Only two triangles are involved in the process of finding, by trigonometrical calculation, the *true* from the *observed* lunar distance.

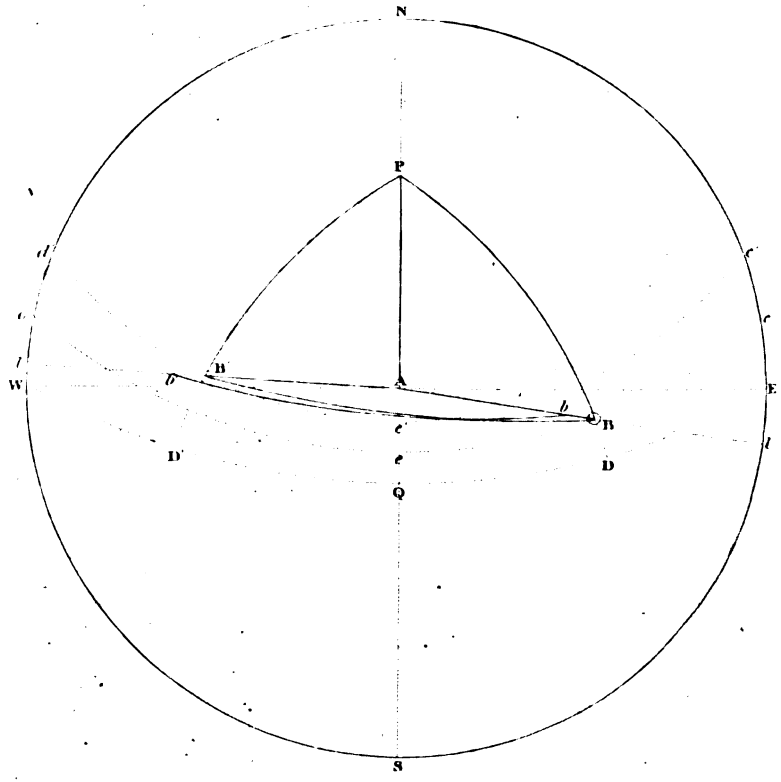
§ *a*. Of the first triangle, the three sides are given; and the angle required is that which is contained at the zenith, between the zenith distance of the moon, and of the other body.

§ *b*. Of the second triangle, this zenith angle and its adjacent sides, are the given parts; and the third side, or true lunar distance, is the part required.

§ *c*. The three sides of the first triangle are the apparent lunar, and the apparent zenith distance of the two bodies.

Digitized by Google

Digitized by Google



Digitized by Google

§ *d*. And the three sides of the second triangle are the *true* lunar and the *true* zenith distances.

§ 470. The *lunar*, or the *true lunar distance* of the sun, or a star, is an arc of a great circle, contained between the centres of either of those objects, and the moon.

§ 471. The distance between the perfect limb (§ 283.), or the round edge of the moon and the near limb of the sun, is the distance usually measured with a sextant.

§ 472. The *apparent* is obtained from the observed distance, by applying, with proper signs, the corrections for the error of the sextant, for the semi-diameters of the two bodies, and for the augmentation of the moon's semi-diameter.

§ *a*. The sun and moon's semi-diameter is given in the ephemeris; the sun's for every 24*h*, and the moon's for every noon and midnight.

§ *b*. The correction for augmentation is found in Table X.

§ 473. *Augmentation* of the moon's semi-diameter, is the difference between the visual angle of the moon's semi-diameter at the centre, and its visual angle at the circumference, of the earth.

§ 474. The difference between these two angles, is proportional to the ratio between the length of the semi-diameter of the earth, and its distance from the moon.

§ 475. On account of its great distance from the earth, the sun's semi-diameter has no sensible augmentation.

§ *a*. As the earth's semi-diameter measures more, in proportion to the moon's geocentric distance, than to that distance of the sun, or of any other heavenly body, the difference of the moon's semi-diameter, when seen from the circumference and from the centre of the earth, is greater than that of any other body, when seen from the same positions.

§ 476. The semi-diameter of the moon, when it is in the horizon, appears under nearly the same visual angle (barring refraction) that it does from the centre of the earth.

§ 477. The moon appears larger, when it is in the horizon, than it does when in the zenith. This though is an optical delusion, for the moon actually subtends the largest visual angle when in the zenith; as it is then nearer to the observer than it is when in the horizon, by a little more than the semi-diameter of the earth.

§ 478. B′ A B represents a diagram of the lunar problem. *b′ b* is the apparent, (§ 472.), and B′ B the true (§ 470.) lunar distance. } Plate 8.

§ 479. The three apparent distances, (*b′ b*, *b′* A, A *b*), are the given parts (§ 469. § *a*.) of the first triangle *b′* A *b*, and the angle *b′* A *b* is the part required in it.

§ 480. The angle *b′* A *b* is common to the second triangle B′ A B, of which the true zenith distances A B, and A B′ are the given, and the true lunar distance B′ B is the required part.

§ 481. The apparent Z. D. of the sun, or of a star, (§ 284. § *a*.) being less, and the apparent Z. D. of the moon (§ 286. § *a*.) being greater, than the true Z. D., it appears from the diagram, that, when the moon's is the greater of the two Z. D., the *true* is always less than the apparent lunar distance.

Digitized by Google

§ *a*. And when the moon's is the less Z. D., the true is sometimes greater, and sometimes less, than the apparent distance.

§ *b*. The *true* is the less when the lunar distance exceeds 90°.

§ *c*. And it is generally the greater, when the distance is less than a quadrant, and the ratio of cos. moon's Z. D. to cos. sun or star's Z. D. is greater than the ratio of rad. to cos. of the lunar distance.

§ 482. The reason why the difference between the apparent and the true L. dist. appears to be governed by the moon more than by the other body, is, that the moon being nearer to the earth, has the greater parallax, and is generally seen further from its true place in the heavens than any other body, from which lunar distances are measured, appears from its true place.

§ 484. By referring to the Nautical Almanac, page xvii., of the ephemeris for Aug. 1834, it will be observed that it was near noon of the 27th at the Greenwich observatory, when the moon was 89° 53′ 24″ from the sun.

§ *a.* If the latitude of the place at which the observation (§ 483.) was made, be known, the time of day at that place, and when the observation was taken, may be found according to the rule § 387.

§ *b.* And the difference (§ 391. § *a.*) between the time of day thus found, and the time in the ephemeris, which corresponds to the calculated lunar distance, is the longitude in time.

difference in the effects of refraction on the upper and the lower limb of the sun and moon; for the moon's parallax in different latitudes, supposing the equatorial to be greater than the polar diameter; and also a correction for the actual barometrical, and thermometrical state of the atmosphere; but at sea, greater errors are unavoidable; hence extreme nicety in these corrections is comparatively of minor importance.

Digitized by Google

§ 485. Distances for determining longitude are always measured from the moon, because the change of the moon's position in the heavens is more obvious than that of any other heavenly body that is visible to the naked eye.

§ 486. The moon (§ 360.) has a daily motion of about 13° 10′ in the heavens; owing to which the moon rises, culminates, and sets, later and later every day, until, having passed through all its phases, it crosses the circle of the sun's altitude, gets to the eastward of the sun, and presents the appearance of a new moon.

§ 487. At a mean, an error of 2′ 12″ in the lunar distance, will produce an error of 1° in the longitude.

§ 488. The moon changes its distance from those bodies which lie directly in its path more rapidly than it does from those towards or from which it moves more obliquely.

§ *a*. Therefore the stars from which the change of the lunar distance for the time being is the most obvious, should be preferred in taking lunar observations; for the more rapidly the distance changes, the less will the longitude be affected by a small error in the observation.

§ 489. In the Nautical Almanac, pages xiii. to xviii. of the ephemeris for each month, contain, at intervals of three hours, the distance of the moon from the sun, from four of the planets, and eight of the principal fixed stars.

§ *a*. The small column, marked P. L., contains the proportional logarithm of the quantity, which the distance preceding it in the left hand column, varies during the three hours between which the P. log. stands.

§ *b*. Table III., pp. 79–94, of this volume, contains the proportional log. for every second of a degree from 1″ to 3°; or for every second of time from 1*s* to 3*h*.

§ *c*. Proportional logarithms are nothing more than the *difference* between the log. of 3 and the log. of any given number less than 3.

Table III.

Thus, the log. of 3 - - - = 0.4771+

Log. of 12′; (12′ reduced to the decimal of a degree is 0.20.) Log. 0.20 (§ 90. § *c*.) = 9.3010+

P. log. of 12′, or 12*m* = 1.1761

§ *d*. This Table is always used for finding the time at Greenwich when a given lunar distance occurred.

Thus, to find the time at Greenwich (§ 293. § *h*.) when the sun was distant from the moon:

Example.

L. Dist. at 6.	84° 17′ 10″	Diff. -	20′ 51″ P. L. = 9362
" at 9.	83° 56′ 19″	Diff. for 3*h* = 1° 20′ 9″	P. L. = 3514
	85° 16′ 28″		
			46*m* 49*s* = 5848

And 46*m* 49*s* added to 6*h*, shows the time (6*h* 46*m* 49*s*) at Greenwich, when the sun was distant from the moon 84° 17′ 10″.

§ *e*. This is a much shorter way than that of arriving at the same result by common logs.; thus,

Digitized by Google

As 1° 20′ 9″ = 1.336 (decm'ls of a deg.)	Ar. co.	= 9.874193
Is to 3*h* - - - -	Log.	= 0.477121
So is 20′ 51″ = 0.3475 (do. of a deg.)	Log.	= 9.540955 (§ 90.)
To 46*m* 49*s* = 0.7803 " "	Log.	= 9.892269 (§ 93. § *g*.)

§ 490. In selecting a star to measure a lunar distance from, that one should be fixed upon whose lunar distance at the time has the *least* p. log. after it in the ephemeris; for, as the greatest variations in the dist. are represented by the smallest p. logs., the lunar dist. of those bodies, which has the smallest p. log. after it, is increasing or decreasing, in a greater ratio, than that is which has after it a greater p. log.; consequently, (§ 488. § *a*.) such bodies are the most favourably situated for determining longitude.

§ 491. When practicable, the distance of the moon should be measured from two stars; one to the east, the other to the west of it; and the *mean* of the longitude resulting from the observations should be taken as the long. of the place.

§ *a*. If the sextant have an unknown error, the error will partially correct itself by its own counteracting effects in distances measured to the east and west of the moon.

§ 492. Latitude by "double altitudes" may also be determined by means of the data in the lunar problem.

§ 493. By inspecting the lunar diagram, it is seen that the arcs (P B, P B′) of the circles of declination of the sun and moon, join the extremities of the true lunar distance (B′ B), forming thereby the triangle B′ P B, of which the three sides are known. Plate 8.

§ *a*. Then the value of the angles P B B′, and A B B′ being found, their difference gives the value of A B P, which, with B A, and B P in the triangle P A B, constitutes data requisite for determining A P, the co-latitude.

§ 494. The lunar problem is one of the most useful and most beautiful problems in navigation; for besides his longitude and latitude, the navigator may deduce, from the principles involved in it, data for the solution of almost any problem in nautical astronomy.

§ 495. The three parts A P, P A B, A P B, in the fourth triangle, are determinable from the data obtained by a lunar observation.

§ *a*. A P is the co-lat. of the place of observation.

§ *b*. A P B is the horary angle, which (§ 382. § *a*.) shows the apparent time of day at the place of observation when the latter was made. And,

§ *c*. The difference between this time (converted into *mean* time,) and the Greenwich time in the N. A. that corresponds to the lunar dist., expresses, in time, the longitude of the place of observation.

Latitude, etc., by Lunars.

§ *d*. P A B is the sun's true azimuth at the time and place of observation; the difference between it and the sun's magnetic azimuth (§ 308. § *a*.) is the variation of the compass.

§ 496. By increasing the triangulation, and extending the operations,

Digitized by Google

other quæsita may be added to the problem; and the length of the day and night; the time of the sun and moon's rising and setting; the hour of the moon's passing the meridian; the hour when each object bears east or west; the duration of twilight; and the amplitudes of the two objects on the day, and at the place of observation, may all be determined by means of the parts involved in the common lunar problem.

§ 497. Therefore when, on account of unknown drifts, and of gales during several days in succession, of thick or cloudy weather, a ship has lost her reckoning, it may be successfully restored by a single lunar observation.

§ *a*. If the variation of the compass be required also at the same time in addition to the lat., time of day and longitude, the calculation, after being conducted into the fourth triangle B A P, should be conducted by a process different from that for evolving the value of A P, the co-lat., alone.

§ *b*. In the latter case, the value of A P would be determined by the rule § *m*. and § *n*., under Case IV. (§ 200.)

§ *c*. And in the former case, the proportion between the sines of

Plate 8. { opposite sides and angles, would evolve it; for, when the three unknown parts of this triangle (B A P) are required, the most direct method of arriving at the required results

consists in applying the rules § *q*. and § *r*., Case IV., (§ 200.) to calculation, in order to determine first the value of the horary and azimuth angles (A P B, and P A B.)

§ *d*. In trigonometrical operations, that method of calculation should ever be adopted, which, being less elaborate, arrives more directly at the required result.

§ 498. When the latitude, etc., is required by means of a lunar observation, the operation of correcting altitudes and of finding the true lunar distance, is conducted as it is under § 483.; and then the value of A B B′ is found before the operation passes from the second triangle B′ A B.

§ *a*. The true lunar distance B′ B being determined, the Greenwich time corresponding thereto is found (§ 489. § *d*.) in the lunar tables of the ephemeris; and then the declination and the right ascension of the sun and moon, at this time, are found in the appropriate tables of the Nautical Almanac.

§ 499. The declination of the two bodies thus found, gives (§ 258. § *b*.) the sides B′ P and B P.

§ *a*. And the difference of their right ascensions (§ 433.), expresses in time the value of the angle B′ P B.

§ *b*. The angle P B B′ is the only part in this triangle, which is required, and it may be found without the trouble of taking from the ephemeris, the right ascension of the two bodies.

§ 500. The true lunar distance (§ 483.) 89° 53′ 24″ of the problem occurred (§ 484.) at Greenwich, August 27, near mean noon, when the sun's declination (page ii. of the Monthly Ephemeris) was 10° 10′ 2″ N.; and the moon's dec. (page v. to xii. do.) was 19° 12′ 39″ N. Their difference in right ascension then was 6*h* 13*m* 52*s*.

§ *a*. And the sun's magnetic azimuth (§ 304. § *a*.) at the time of observation, was N. 109° 4′ 30″ East.

Digitized by Google

§ 501. The apparent and true zenith distances are found, and the calculation for determining the true lunar distance (B′ B) is conducted precisely in the same manner, as it is (§ 483.) when the true distance is the only object of the problem.

§ 503. If the latitude and time of day, without the variation, be required from a lunar observation, the process of calculation may be varied from that above for finding the azimuth, time, and latitude; and may be made more direct.

§ *a.* But in either case, the order and method of calculation are the same, in the process of arriving at the value of A B P in the fourth triangle.

§ 504. The true lunar distance (B′ B) must always be determined, before the correct P. distances, (P B, P B′) and the difference (B′ P B) in right ascension (§ 498. § *a.*) of the two bodies, can be known.

§ *a.* These parts must always be taken from the ephemeris, and for the time in it, which corresponds to the true lunar distance.

§ 505. Having found, in the second triangle, the required angle A B B′; then having taken (§ 498. § *a.*) from the ephemeris, the proper P. D., etc., and calculated (§ 502. § *a.*) the value of the angle (P B B′) required in the third triangle; the value of A B P is obtained, and the lat. and time of day may thence be deduced by the following formula.

§ 506. *Formula for latitude and time of day by a lunar observation.*

§ 507. If the second and third triangles fall on opposite sides of the lunar distance B′ B, then the sum of the angles (A B B′ & P B B′) of the second and third triangles, gives the value of the required angle (P B A) of the fourth triangle. Plate 8.

§ 508. When the polar distance of each body is greater than the co-latitude of the observer, then the second and third triangles fall upon the same side of the lunar distance B′ B, and the difference between the angles (A B B′, P B B′) is the value of the angle (A B P) sought in the fourth triangle. Plate 9.

§ 509. It may always be known, whether the sum or difference of the angles of the second and third triangle, will give the angle required to be known in the fourth triangle, by observing the inclination of the plane in which the sextant is held to bring the sun and moon in contact when making the observation:

§ *a.* If the sextant be inclined to the plane of the horizon, towards the pole of the observer, then his co-lat. is greater than the P. dist. of either body, and the second and third triangles fall upon different sides of the lunar distance, and the sum of the two angles is the required angle of the fourth triangle.

§ 510. May 16, (P. M.), 1834.

§ 511. Examples under § 483. and § 510. are drawn out in the solution, in order to familiarize the problem to the student. But such a process of calculation as is there shown, is not desirable in practice; especially that part of it which has been made to come under Case IV., (§ 200.) on account of the perplexity in determining whether the value of the auxl. *a* be greater or less than 90°.

§ *a.* Therefore, in practice, those methods of calculation are generally preferred, which give the trigonometric function of *half* the value of the required part, such as § *a.* (§ 386.); for *half* the value of a required arc or angle should never exceed 90°.

§ 512. The learner has now become familiar with the triangulation, which is brought under calculation in the process of finding longitude, etc., from a lunar observation; he will therefore readily comprehend the manner by which such an operation is simplified, and reduced to the following methods and formulæ for practice.

§ 513. The process of correcting the obs. distance and altitudes is fully shown under § 483. and § 510. This part of the operation is the

LATITUDE BY THE NORTH STAR.

§ 515. In northern latitudes, the latitude may be found at any time of the night, by an altitude of the north star.

§ 516. If the north star were situated in the pole of the world, its altitude would always show the elevation of the north pole; and (§ 251. § *a.*) consequently the latitude of the observer.

§ 517. But the declination of this star, at a mean, is about 88½°, with a small variation.

§ *a.* Being, therefore, so near the pole, it revolves about it in a very small circle, and its altitude can never differ from the elevation of the pole, (which (§ 251. § *a.*) is the latitude of the observer,) more than the star's polar distance.

§ 518. The right ascension of the north star, called Polaris, is about 1*h* 4*m*. That is, Polaris is on the meridian of the observer wherever he be, always a few minutes after 1*h*, sidereal time. (§ 261.)

§ *a.* And though the altitude of the star varies with the latitude, yet the *change* of altitude (§ 409. § *b.*) during the day, or for any portion of the day, is nearly the same for all navigable latitudes. Thus with us, in N. lat., with whom Polaris never sets, its meridian alt. is 1° 30′ (*nearly*) greater than the lat., and 12 hours afterwards its altitude when on the lower meridian is 1° 30′ (*nearly*) less than the lat., *i. e.*, the *change* of alt. is twice the P. distance of the star, (say 3°).

§ 519. Proceeding upon these principles, it is easy to calculate the reduction to the meridian (§ 409. § *a.*) of Polaris whenever the sidereal time of observation be known.

§ *a.* The difference of the given sidereal time and 1*h* 4*m* (§ 518.) is the hour angle—and with the lat. and declination given, we have the two sides and their contained angle (§ 200.) of a spherical triangle to determine the third side, or the Z. D. of the star.

§ *b.* The difference between this Z. distance and the meridian Z. dist. of the star, (1° 30′) (§ 518. § *a.*,) gives the required reduction to the meridian; which reduction (§ 518. § *a.*) answers for that hour angle in all latitudes.

§ *c.* Upon these principles the annexed table (p. 238.) has been calculated. It is not strictly *correct*. But considering that the altitude of Polaris can seldom be accurately taken from the *sea* horizon—for the star is between the 2d and 3d magnitude—this table affords a very simple

TIDES.

§ 525. The flux and reflux of the waters, known under the name of Tides, are said to be caused by the attractive forces of the sun and moon exerted upon the ocean.

§ 526. The moon being nearer to the earth than the sun is, has a greater effect than the sun has upon the tides.

§ *a.* The action of the moon upon the tides, is about three times greater than that of the sun.

§ 527. When the attractive forces of the sun and moon act in conjunction, they produce the highest tides.

§ *a.* When this is the case, the moon (§ 367.) is in syzygy.

§ *b.* And the tides caused about this time are called *spring* tides.

§ 528. The tides have the least rise and fall, when the attractive forces act perpendicularly to each other.

§ *a.* And this is the case, when the moon (§ 369. § *b.*) is in quadrature. Then the tides are called *neap* tides.

§ 529. During the interval between two consecutive transits of the moon across the same meridian (§ 362. § *a.*), the tide rises twice, and falls twice, at the same place.

§ 530. The attractive forces of the sun and moon upon equal portions of the surface of the sea, being (§ 526. § *a.*) about 3 to 1 in favour of the latter; if the solar tide at any place be 2 feet and the lunar 6, and

Digitized by Google

the moon be in syzygy, the two tides will happen at the same time, and (§ 527. § *b.*) make a spring tide of 8 feet.

§ *a.* Then, as the lunar (§ 360. § *a.*) is longer than a solar day, the following solar will happen earlier than the succeeding lunar tide, by the difference between half a solar and half a lunar day.

§ *b.* Thus, the lunar tide continues to retard upon the solar tide, until the moon quadrates; when the high lunar and low solar tides coincide in time, and (§ 528. § *a.*) we have in the case supposed (§ 530.) a neap tide of four feet rise.

§ *c.* After this, the lunar still continues to retard upon the solar tide, until the moon arrives in the other syzygy; when the two high tides again happen at the same time, and bring about other spring tides.

§ *d.* At this second spring tide, the moon has completed half of a revolution in its orbit, and has lost one tide upon the sun; therefore, while the moon is completing one entire revolution through its phases, there are two more solar, than lunar, tides.

§ 531. At some places, the passage of the moon across the meridian, precedes, by several hours, the time of high water.

§ *a.* This retardation of the tides might be explained, by attributing the retarding power to the effects of the resistance, which the shores, unequal depths of ocean, etc., offer to the tidal wave, were it not that the waters do not rise up into spring tides, when the moon is in syzygy, and when the attractive forces of the sun and moon are combined in their action upon the waters; but the highest tides in every synodical month (§ 362. § *c.*), is generally about the third tide after the passage of the moon through either syzygy.

§ 532. And the least neap tide, is generally the third tide after the moon quadrates.

§ 533. Observations show, that the tides require a little longer time to ebb, than they do to flow.

§ *a.* This difference observable at sea, becomes more obvious in rivers of strong currents.

§ 534. Upon the smaller seas, and sheets of water, such as the great northern Lakes, the Mediterranean, etc., the effect of the lunar and solar attractions, is partially counteracted by the circumscribed limits to their action; and hence but little or no tide is produced there.

§ 535. There are a variety of causes, (and some of a local nature,) which, acting together, tend, some to retard at one place, and others to hasten at another place, the hour of high tide on the full and change days of the moon; so that there are no general rules for determining, beyond certain limits of mere approximation, the time of high or low water at any place.

§ 536. The greatest interval between two consecutive tides, generally happens about a day and a half after the moon has quadrated; when the tides, (§ 532. § *c.*) being at the minimum of their rise and fall, are the weakest.

§ *a.* And the least retardation of one tide after another, is the 2d upon the 3d, or the 3d upon the 4th tide, after the moon's latest passage through a syzygy; the tides, having then (§ 532. § *b.*) the greatest rise and fall, are strongest.

Digitized by Google

§ 537. On an average, the tides rise and fall once in about $12h\ 24m$.

§ *a*. Consequently every tide retards, at a mean, about $24m$, upon the one which it succeeds; and each tide happens about $48m$ later than it did the day before.

§ 538. Were there not so wide a difference in the tides, between the minimum and maximum of their retardation, the hour of high or low water, at any place and on any day, might be found by adding to the time of high water on full or change days, the product of $48m$, and the number of days from the latest full or new moon, to the day proposed.

§ *a*. About the time of neap tides, there is sometimes a difference of more than an hour and three quarters in the time of high water, on two successive days.

§ *b*. And a similar difference about the time of spring tides, is frequently less than half an hour.

FINDING THE TIME OF HIGH WATER.

§ 539. The annexed table (C, p. 242) shows the retardation of the *mean* tides, upon the hour of high tide on full and change days, for every day between the full and change of the moon.

§ *a*. Therefore, to find the time of mean high water on any day, we have only to look in the Nautical Almanac (page xii. M. Ephemeris,) for the day of the latest new, or full moon, in order to find its age (in days) since the last change in syzygy; the time, in the annexed table (C), found opposite to this age, and added to the time, gives of high water at the place proposed, on full and change days, the time of mean high tide for the day when it is so required. } *Rule.*

§ *b*. The hour of high tide at any port, on full and change days, is called the *establishment* of the port.

§ *c*. And the *establishment of the port* for any *one* place is always the same; for on every full and change day throughout the year, high tides are considered to take place there at the same hour of the day.

NAVIGATION.

§ 542. The geographical situation of places is designated by their distance, north or south, from the equator; and by their distance, east or west, from a prime meridian (§ 252. § *c.*)

§ *a.* These distances (§ 248. § *b.* and § 252.) are known by the name of Latitude and Longitude of the places.

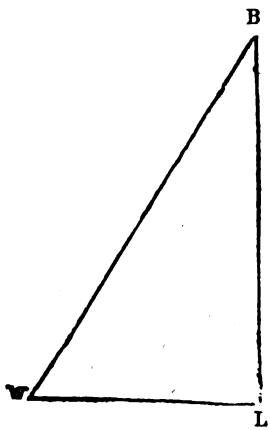
§ 543. It has been shown in Nautical Astronomy, how the latitude and longitude of places may be determined by means of observations made upon the sun, moon, or stars; but in practice these means are not always at hand.

§ *a.* It remains then to be shown, how the geographical position of places may be determined, by knowing, in certain respects, their relative situation with regard to each other.

§ 544. Washington city is to the southward and westward of Baltimore. The difference of latitude between them (§ 254. § *c.*) is the meridional arc, which is contained between Baltimore and the parallel of the latitude of Washington.

§ *a.* And the arc of this parallel which is between Washington and the meridian of Baltimore, (§ 254. § *b.*), is the difference in longitude between the two places.

§ *b.* These two arcs are perpendicular to each other; for the meridian of Baltimore (§ 248. § *a.*) cuts the equator at right angles, and the parallel of Washington (§ 249.) is parallel to the equator.



§ *c.* Now, if a line (W B) be drawn direct from Washington to Baltimore, it will connect their difference of longitude (W L) and of latitude (B L), and form a right angled triangle (W L B), of which the hypothenuse (W B) is the distance; and the legs, the difference of latitude and of longitude, between Washington and Baltimore.

§ *d.* The two acute angles (W and B) show the bearings of each place from the other. The angle W is the course from Washington to Baltimore, and the angle B is the course from Baltimore to Washington.

§ *e.* Hence, if of the Dist., Diff. Lat., Diff. Long., and Course, between two places, any two be given, the others are determinable.

Digitized by Google

§ 545. Now, the section of a loxodromic curve, which a ship traces while she is sailing upon a given course, may be considered as the hypothenuse of a right angled triangle, which corresponds to W B.

§ *a.* Then if the course and distance, which a ship sails in any given time, be known, we have the hypothenuse and an acute angle of a right angled triangle, given; and the other parts are determinable.

§ *b.* Therefore, knowing the latitude and longitude of the place from which a ship takes her departure, and knowing the course and distance which she sails from that place, in a specified time, we may determine by right angled trigonometrical calculations, the latitude and longitude of the ship, at the end of that time.

§ 546. The sides of all such triangles are curved lines; for the earth (§ 204.) is a spheroid; therefore all triangles upon its surface are spherical triangles, and are properly subject to the rules of spherical trigonometry, for investigation.

§ *a.* But the laborious operations of obtaining results from these triangles, when brought under calculation, as spherical triangles, would be inconvenient in practice; and they are not necessary in the ordinary purposes of navigation.

§ *b.* Therefore all such triangles are considered in navigation as right angled plane triangles, and are brought under calculation according to the rules of plane trigonometry.

§ 547. A degree (°) of all great circles, such as the equator, meridians of longitude, etc., whose radii and the earth's semidiameter are the same, consists of 60 *nautical miles*, or of about 69½ statute miles; so that, calling the number of minutes (′), miles, which are contained in an arc of one of these great circles, we have the value of this arc considered as a straight line.

§ *a.* And, knowing the distance and the difference of latitude between any two places, the difference of longitude between them may be determined also in *nautical* miles, by right angled, plane trigonometrical calculations founded upon § 75.

§ *b.* The difference of longitude thus found, is called departure.

§ 548. *Departure* is the difference in longitude between any two places, expressed in *miles.*

§ *a.* And the departure in any latitude, may be converted into its corresponding minutes (′) of longitude by means of the principles established under § 76.

§ 549. It is evident, that, if in mathematical calculations, curved lines be treated as right lines, there must be an error in the result; and this error increases with the number of degrees contained in such curved lines.

§ 550. The result, then, obtained by calculating the sides of a spherical triangle, as though they were the straight lines of a plane triangle, is only an approximation; and the smaller the sides, the closer is the approximation.

§ *a.* This method, therefore, is particularly applicable in small distances, and short runs; it is used for working up "dead reckoning," and for calculating the distance, the difference of latitude and of longi-

Digitized by Google

tude, and the course from one place to another; any two of which four quantities being known, (§ 544. § *e.*,) the others are determinable.

§ 551. The diagram shows by a mere inspection, the solution of every problem which can occur in right angled plane trigonometry, provided the hypothenuse of the triangle involved, do not exceed 300 miles, or 300 units of any measure. Plate 1.

§ *a.* This diagram may answer the purpose of Tables IV. and V.; and it also shows the principles upon which they are constructed; for the number in the Dist. column of these tables, is the length of the hypothenuse of a right angled triangle, whose acute angles contain, one the number of degrees at the top, and the other those at the bottom of the page, and the value of whose legs is set down opposite to that of the hypothenuse, and in the columns marked Dep. and D. Lat.

§ 552. This diagram, then, shows the solution of every case, or problem, in loxodromic sailing; for it shows the dimensions of the triangle involved in every problem, provided the distance or hypothenuse do not exceed 300 miles.

§ *a.* If it exceed 300 miles, the solution may be obtained by dividing the given side or sides, by 2 or 3, or by any other divisor, which will reduce the triangle of the problem within the limits of the diagram; then the value of the side or sides, obtained, by using said quotient in the diagram, being multiplied by the same divisor (§ 70.), gives the value of the required side or sides.

§ 553. The angle B A D is 45°.

§ *a.* The acute angles of a right angled triangle (§ 32. § *d.*) being complementary to each other, the less must always be located at A.

§ *b.* And the leg adjacent to it must be called the *base*, and be a part of A D.

§ *c.* And the leg opposite to it must be called the *perpendicular.*

§ *d.* All the straight lines standing upon A D, are alluded to as *perpendiculars.*

§ *e.* B C is the greatest *perpendicular* in the diagram. Equal portions of it are transferred by means of the parallels *b d*, to the graduated arc B D, for admeasurement.

§ *f.* The graduated arc B D is thus made to answer the purpose of a graduated *perpendicular*, for the arc contains the same divisions which the *perpendicular* B C would have shown, had it been graduated to the scale of A B and A D.

§ *g.* The height of every *perpendicular* is therefore shown on that portion of the graduated arc which is between the *base* (§ *b.*) and that parallel under which the *perpendicular* stands. Thus the height of the *perpendicular b* C, transferred by the parallel *b d*, to the graduated arc, is D *d* = 11.3.

§ 554. The arcs in the diagram show the angular value of any course, provided it be not more than 4 Points, or 45°.

§ *a.* If the course be greater than this, they show the angular value of its complement.

§ *b.* The arcs, 3, 4, 5, etc., also show the length of the *base* and hypothenuse of the triangle proposed; while the scale on the graduated arc (§ 553. § *g.*) shows the value of the *perpendicular* (*b c*) in the several triangles.

Digitized by Google

The Diagram.

Plate 1. § *c.* The section of any arc, which is contained between the *base*, and the lines A *e*, shows the angular value of the courses which are marked *upon* these lines; and the angular value of the complements (§ 553. § *a.*) of the courses, marked *under* these lines.

§ *d.* The marks on the arcs show the value of these arcs in degrees.

§ *e.* The even numbers (2°, 4°, 6°, etc.) of degrees are marked on the concave side of the arcs; and the odd numbers, (1°, 3°, 5°, etc.) are marked on the convex side.

§ *f.* The degrees (46°, 47°, 48°, etc.) that stand on the outside of the graduated arc, are the complements of those (42°, 43°, 44°, etc.) on the inside of the arc.

§ *g.* The entire length of every arc (§ 553.) is 45°.

§ 555. The dotted lines A *e'*, represent quarters of points; the broken lines A *e*, represent halves of Points; and the continuous lines A *e*, whole Points.

§ *a.* The distance on a given course is shown on the lines A *e*, at the end of which lines that course is found; then the portion of that line (A *e*) which is contained between A, and the arc 3, 4, etc., which is marked with the distance proposed, is hypothenuse to the triangle required.

§ *b.* Thus 24 miles on a $2\frac{1}{2}$ Point course, is the distance A *b* on the broken line A *e*, at the end of which $2\frac{1}{2}$ is marked; and A C *b* is the right angled triangle, of which the course and the distance proposed constitute an angle and the hypothenuse.

§ *c.* The two legs of this triangle are the *base* A C, and the *perpendicular b* C which stands under the parallel *b d*.

§ *d.* The graduated scale on A D shows the value of A C = 21.1, the D. lat.; and the portion (D *d*) of the scale on the graduated arc, between the *base* and the parallel *b d* (§ 553. § *g.*), shows the height of the *perpendicular b* C = 11.3, the Dep.

§ 556. Now as the distance which a ship may sail upon any loxodromic course, is considered (§ 546. § *b.*) as the hypothenuse of a right angled plane triangle, if the distance sailed upon such course can be found in the diagram, the departure and difference of latitude, which correspond to that course and distance, may be found by means of the graduated *base* and arc, A D and B D.

§ *a.* Or, if any two of these quantities, viz., Course, Dist., Dep., and Diff. Lat., be known, the other two are determinable by means of the diagram.

Examples. § 557. A ship sails N. W. ¼ N. 19 miles, What departure and difference of latitude does she make?

§ *a.* The given course is found *upon* the dotted line A *e'*, and that portion (A *b*) of this line, which is between A and the 19th arc, is the hypothenuse of the triangle (A *c b*) involved.

§ *b.* The *perpendicular* (*b c*) intersects the *base* at 14.1, which is the difference of latitude.

§ *c.* And the parallel, from the top of the *perpendicular*, intersects the graduated arc at 12.7, which is the departure.

Digitized by Google

Plate 1. Examples.

§ 558. A ship sails N. W. by N. and makes 12.7 miles of departure, What distance and diff. lat. does she make?

§ *a.* The parallel from 12.7 on the graduated arc, intersects the N. W. by N. line, in the point, (nearly), where the 23d arc crosses it; then nearly 23 (22.9) miles is the distance sailed.

§ *b.* And the *perpendicular* from this point of intersection, falls upon the *base*, and shows the difference of latitude required, to be 19.1 miles.

§ 559. A ship sails N. by W. $\frac{3}{4}$ W. and makes 19.8 miles diff. lat., What departure and distance does she make?

§ *a.* The *perpendicular* at 19.8 on the *base*, being traced up, is found to intersect the N. by W. $\frac{3}{4}$ W. line on the 21st arc; then 21 miles is the distance sailed.

§ *b.* And the parallel from this point of intersection, being traced to the graduated arc, shows the height of the perpendicular 7 miles, which is the departure required.

§ 560. A ship, after sailing 18 miles, finds that she has made 16.2 miles diff. lat., What course did she sail, and what departure has she made?

§ *a.* The *perpendicular* from 16.2 on the *base*, intersects the 18th arc on the dotted line marked $2\frac{1}{4}$ Points, which is the course required.

§ *b.* And the parallel from this point of intersection, shows, on the graduated arc, the height of the perpendicular to be 7.8 miles, which is the departure required.

§ 561. A ship sails 28 miles, and finds that she has made 15.6 miles departure, What course and diff. lat. has she made?

§ *a.* The parallel from 15.6 on the graduated arc, cuts the 28th arc, on the line marked 3 Points, which is the course sailed.

§ *b.* And the *perpendicular* from this point of intersection, falls upon the *base* at 23.3 miles, which is the diff. lat. required.

§ 562. The departure between two places is 8.7 miles, and the diff. lat. between them is 28.6 miles, What is the course, and the distance from one place to the other?

§ *a.* The *perpendicular* from 28.6 on the *base*, intersects the 30th arc on the broken line, $1\frac{1}{2}$, which shows the required course and distance to be $1\frac{1}{2}$ Points, and 30 miles.

§ 563. If the distance sailed be not more than a mile, or if the hypothenuse of the triangle proposed be not greater than 3 miles, the divisions on the scales must be decimated; then the figures 1, 2, 3, 4, 5, etc., stand for $\frac{1}{10}$, $\frac{2}{10}$, $\frac{3}{10}$, $\frac{4}{10}$, $\frac{5}{10}$, etc., and the subdivisions stand for 100ths.

§ *a.* Wherefore, when the distance is not more than 3 miles, the distance from A to the 10th arc, is 1 mile; to the 20th, 2 miles; and to the 30th, 3 miles; and all the intermediate numbers in the diagram stand for 10ths.

§ 564. What departure and difference of the lat. would a ship make by sailing 2 miles N. W. $\frac{1}{2}$ N.?

§ *a.* The parallel and *perpendicular* which would pass through the point in which the 20th arc intersects the N. W. $\frac{1}{2}$ N. line, measured by the eye, would cut the graduated arc and base in 12.7 and 15.4.

§ *b.* And using only one decimal place (§ 563.), the nearest would

Digitized by Google

be 1.5 diff. lat. and 1.3 departure; but the exact is 1.54 and 1.27 diff. lat. and dep.

Examples.

Plate 1. § 565. When the lines in the diagram do not pass through the point required by the conditions of the triangle involved, the imaginary lines required, may be traced by the eye with all the precision which is necessary; and after a little practice, with the utmost facility.

§ *a.* Thus, the distance of one place from another, is N. by W. 27½ miles; the triangle involved in this problem, being filled up by the eye, the imaginary parallel and *perpendicular*, cut the graduated arc and *base* in 5.3 and 27; which shows the departure between the two places to be 5.3 miles, and the diff. lat. 27 miles.

§ 566. If the distance sailed on a single course exceed 30 miles, or the hypothenuse of the triangle involved, be greater than 30 miles, all the numbers in the diagram must be increased tenfold.

§ *a.* Then the arcs must be reckoned as being 10 miles apart; the numbers 1, 2, 3, 4, 5, etc., will stand for 10, 20, 30, 40, 50, etc.; and the distance between these numbers being divided, every one into 10 equal parts, each one of these subdivisions must be counted as 1 mile.

§ 567. A ship sails N. W. 240 miles; what departure and diff. lat. does she make?

§ *a.* The parallel and *perpendicular* from the intersection of the 24th arc (now counted (§ 566.) 240), with the N. W. line, cuts the graduated arc and *base* (§ 41.) at equal distances, and the departure and diff. lat. (§ 14.) are the same.

§ *b.* Departure = 169.5. diff. lat. = 169.5. This is $\frac{3}{10}$ of a mile less than the result by logarithmic calculation. This difference is owing to the smallness of the scale upon which the diagram is projected, and not to any defect in the principles involved in the projection of the diagram.

§ 568. In the examples quoted above, the courses are *on* the lines, and the diff. lat., except (§ 567.) when the course consists of 4 Points, is always greater than the departure.

§ 569. The courses and figures *under* the lines (§ 554. § *e.*) are the complements of those *on* the line above them; and when the course is found *under* the line, the departure is the longest leg of the triangle involved, and must be read off upon the base A D; and the diff. lat. is taken from the graduated arc B D.

§ *a.* A ship sails E. ¼ N. 28 miles. What departure and diff. lat. does she make?

§ *b.* The parallel and *perpendicular* which pass through the point where the 28th arc cuts the dotted line, *under* which the given course is marked, meet the graduated arc and base in 1.3 and 27.9+.

§ *c.* Then (§ 569.) the departure = 27.9, and the diff. lat. = 1.3.

§ 570. The four cardinal points of the horizon (§ 272.) divide it into four quadrants, each containing 8 Points.

§ *a.* Wherefore a Point = 11° 15′, (the quotient of 90° by 8.)

§ 571. The Points, when expressed by numbers, begin at the north and south, and are reckoned in numerical order, to the east and west points.

Digitized by Google

§ *a*. Hence, it is easy to conceive that a vessel that sails N. 3 Points W., or N. W. by N., would make more *northing* than *westing*, and that her diff. lat. would be greater than her departure.

§ *b*. And conversely, that if a vessel sail on any course between 4 and 8 Points, e. g., N. 5 Points W., or N. W. by W., she would make more *westing* than *northing*, and that consequently her departure would be greater than her diff. lat.

LOXODROMIC SAILING.

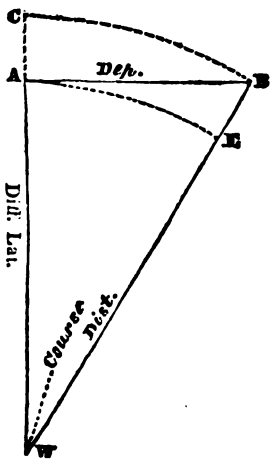
§ 572. From what has already been advanced in explanation of Plate 1, it appears that the triangle involved in the trigonometrical solution of any problem in *loxodromic* sailing, is a right angled plane triangle.

§ *a*. *Loxodromic* sailing,* is so called from the sort of curve which the track of a ship forms, when she is sailing upon any course not exactly due east or west, north or south.

§ *b*. *Loxodromic* curves are spirals, which continually approach the poles, but can never reach them.†

§ *c*. And any course, not due east or west, north or south, is called a loxodromic course.

§ 573. A number of formulæ, varied in the trigonometric functions to be used, may be drawn up for the solutions of the several cases in loxodromic sailing.



§ *a*. The terms in these formulæ depend upon the side of the triangle, (whether it be the distance, the departure, or diff. lat.,) which is made radius.

§ 574. Baltimore is 35 miles N. N. E. $\frac{3}{4}$ E. from Washington. The formula for finding by calculation the departure and diff. lat. between the two places, depends upon the trigonometrical construction which is given to the triangle involved.

§ *a*. If the hypothenuse be made radius to an arc B C, the dep. becomes (§ 54.) sine to the course, and the diff. lat. its co-sine.

§ *b*. Then, (§ 75.,) rad. : dist. : : sine of course : dep. : : cos. course : diff. lat.

§ *c*. Hence (§ 74.) are deduced the following formulæ; the three first being the given terms, and the fourth, the unknown and required term, of the proportion.

* The subdivisions of the *sailings*, viz., Plane, Traverse, Parallel and Middle Latitude Sailing, are not here preserved. These distinctions are by no means necessary for the purpose of facilitating the navigator's calculations; they have therefore been generalized under the term of *loxodromic sailing*.

† E. by N. is a loxodromic course. Suppose a vessel could sail E. by N.

FORMULÆ.

§ *d.* Sine course : dep. : : rad. : dist. (§ 75. § *b.*).
§ *e.* Dist. : rad. : : dep. : sine course.
§ *f.* Cos. course : diff. lat. : : rad. : dist.
g. Dist. : rad. : : diff. lat. : : cos. course.
§ *h.* Cos. course : diff. lat. : : sin. course : dep.

Examples.

§ *i.* Dist. 35. log. = - - - 1.544068
Course = $2\frac{3}{4}$ pts. (§ 571.) sine (Table D.)=9.711049 (p. 254.)

Log. dep. = 1.255117=18 miles.

§ *j.* Dist. 35 log. = - - - 1.544068
Course, $2\frac{3}{4}$ pts. cos. = - - - 9.933350 (p. 254.)

Log. diff. lat. = 1.477418=30 miles.

§ 575. If the triangle be constructed upon the diff. lat. as radius of the arc A E, then the dist. becomes (§ 57.) secant, and the dep. (§ 56.) tangent, to the course.

§ *a.* And (§ 75.) sec. course : dist. : rad. : : diff. lat. : : tang. course : dep.

§ *b.* Wherefore, the diff. lat. being taken as radius, the following formulæ are derived either (§ 75. § *c.*) immediately from the construction of the triangle, or (§ 67. § *e.*) from the relation of the terms, as they are expressed in the proportion § *d.* (§ 98.)

FORMULÆ.

§ *c.* Diff. lat. : rad. : : dist. : sec. course.
§ *d.* Rad. : diff. lat. : : sec. course : dist.
§ *e.* Diff. lat. : rad. : : dep. : tang. course.
§ *f.* Tang. course : dep. : : rad. : diff. lat.
§ *g.* Tang. course : dep. : : sec. course : dist.

Examples.

§ *h.* Course $2\frac{3}{4}$ pts. cos. = 9.933350 (§ 101. § *b.*) (p. 254.)
Dist. 35 miles, log. = 1.544068

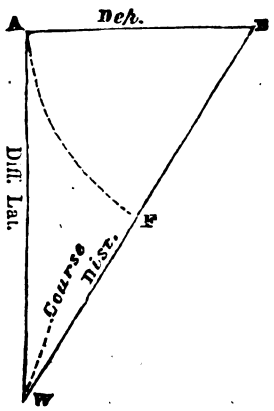
Log. diff. lat. = 1.477418 = 30 miles.

Course $2\frac{3}{4}$ pts. cos. = 9.933350 (p. 254.)
Dist. 35 miles, log. = 1.544068
Course $2\frac{3}{4}$ pts. tang. = 9.777700

Log. dep. = 1.255118 = 18 miles.

without any obstruction, or without ever deviating from that course; the N. pole would then be always *one Point* forward of her beam. It is difficult to imagine how a vessel could ever arrive at such a point.

Digitized by Google



§ 576. Or if the triangle be constructed upon the dep., as radius of the arc A F, the dist. becomes secant, and the diff. lat. the tangent, of B, the complement (§ 32. § *d.*) of the course.

§ *a.* Wherefore (§ 75. § *c.*) co-sec. course : dist. : : rad. : dep. : : co-tang. course : diff. lat.

§ *b.* Other formulæ, similar to those under § 575., might be drawn out here, but these for the most part would be a repetition of those, as the expression 4×6 is a repetition of the form 6×4 of multiplication. Indeed several sets of the proportions under § 574. and § 575., are similar repetitions of each other. (Vide § 98.)

§ *c.* Course $2\frac{3}{4}$ pts. sine = 9.711049 (§ 101. § *b.*) (p. 254.)
Dist. 35 miles, log. = 1.544068

Log. dep. = 1.255117 = 18 miles.

§ *d.* Course $2\frac{3}{4}$ pts. sin. = 9.711049
Dist. 35 miles, log. = 1.544068
Course $2\frac{3}{4}$ pts. co-tang. = 0.222300

Log. diff. lat. = 1.477417 = 30 miles.

§ 577. The principles of the above trigonometrical construction are also developed in the solution of problems by the diagram. } Plate 1.

§ *a.* Thus, to find the course and dist. which correspond to 12 miles diff. lat., and 5 miles dep.

§ *b.* The *perpendicular* which cuts the *base* in 12, is tangent to the 12th arc, and A 12 is its radius.

§ *c.* The parallel from 5, on the graduated arc, cuts this *perpendicular* on the 13th arc, at its intersection with the 2 Point line, and A 13 is secant to the course (2 Points) and the dist. required.

§ *d.* If the dist. A 13, on the 2 Point line be called radius of the 13th arc, then the portion of the *perpendicular*, between the point of this intersection, is sine of the course, and A 12 on the *base*, is its co-sine.

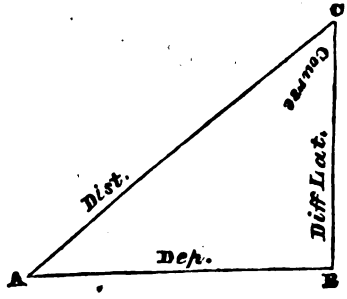
	Co-sine.	Sec.	Sine.	Co-sec.	Co-tang.	Tang.	Points.

§ 579. In every case, except when the dep. and diff. lat. constitute the two given parts, the solution of the problem proposed, may be obtained by means of the proportion (§ 74.) between the sides of a triangle and sines of its opposite angles.



§ *a*. In the triangle A B C (§ 74.) right angled at B, (§ 74.) dist. : sine B = 90° : : dep. : sine course; but the sine of 90 (§ 62.) is radius, wherefore we have again the formula § *e*., (§ 574.), viz., dist. : rad. : : dep. : sine course, and a repetition of others under § 574.

§ 580. Some one of the following formulæ (*rejecting or borrowing* 10 *for rad.*, (§ 101. § *b*.,) *in the index of the second member of the equation*), may be used in every case where two of the four quantities, dist., course, dep. and diff. lat., are given.

FORMULÆ.

§ *a*. Dep. (§ 574. § *b*.) = dist × sine course.
§ *b*. Dep. (§ 575. § *e*.) = diff. lat. × tang. course.
§ *c*. Diff. lat. (§ 574. § *j*.) = dist. × cos. course.
§ *d*. Diff. lat. (§ 575. § *f*.) = $\frac{\text{Dep.}}{\text{tang. course}}$ (§ 101. § *b*.) = dep. × cot. course.

Digitized by Google

§ *e*. Dist. (§ 575. § *d*.) = diff. lat. × sec. course.
§ *f*. Dist. (§ 576. § *a*.) = dep. × co-sec. course.
§ *g*. Sin. course (§ 574. § *e*.) = $\frac{\text{Dep.}}{\text{dist.}}$
§ *h*. Cos. course (§ 574. § *g*.) = $\frac{\text{Diff. lat.}}{\text{dist.}}$
§ *i*. Tang. course (§ 575. § *e*.) = $\frac{\text{Dep.}}{\text{diff. lat.}}$
§ *j*. These formulæ will always be found convenient in practice.

OF TURNING DEPARTURE INTO DIFF. LONG.

§ 581. If the difference of longitude between two places (§ 548.) be expressed in miles, it is called *Departure*.

§ *a*. A minute of longitude is nowhere, except at the equator, equal to a mile of departure; for the distance between any two meridians of longitude (§ 248. § *a*.) is greatest at the equator, and the least about the poles.

§ *b*. Therefore the dep. between any two meridians is greater at the equator than in any latitude.

§ *c*. Furthermore, as all meridians (§ 248. § *a*.) intersect at the poles, the dep. between any two becomes less and less, as you approach the poles, where there can be no dep.; whereas the difference of longitude, between these meridians in any latitude, (§ 254. § *a*.) is the same, being expressed by the same number of degrees (°), minutes (′), etc.

§ 582. Suppose two places to be situated in the same latitude, the arc of this parallel of latitude, contained between them, (§ 254. § *b*.) is their difference in longitude.

§ *a*. And parallels of latitude (§ 249.) are small circles.

§ *b*. Suppose also an arc of a great circle (§ 122.) to be drawn from one of these places to the other, this arc (§ 122. § *a*.) would be the shortest distance between the two places, and the minutes (′) contained in it, would show (§ 547.) the departure between them.*

§ 583. These two arcs are contained between the same two points, and (§ 76.) the arcs are to each other, as the radius of the great circle is to the radius of the small circle.

§ *a*. The rad. of such a great circle, as well as of the equator, etc., (§ 122.) is semi-diameter to the earth.

§ *b*. And the radius of the small circle, or the parallel, (§ 130. § *a*.) is the cos. of its latitude.

§ 584. Then, calling the semi-diameter of the earth, unity, or rad., we have (§ 76.) for any latitude; diff. long. : dep. : : rad. : cos. lat.

§ *a*. Also cos. lat. : dep. : : rad. : diff. long.

§ *b*. And rad. : diff. long. : : cos. lat. : dep.

* Hence it appears that the *course* between two places, is never the shortest distance between them, unless they be either upon the equator, or upon the same meridian.

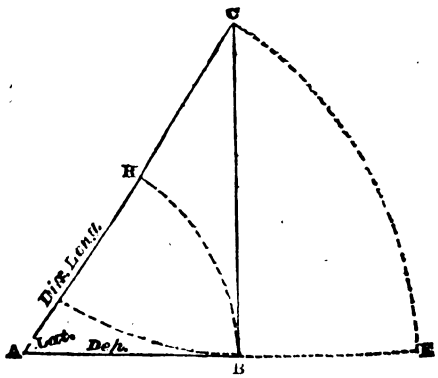
Digitized by Google

§ *c*. Wherefore, if any two of these three quantities, (rad. is always known), be given, the other and remaining one is determinable.

§ 585. The terms of these proportions represent quantities, comprised in the elements of a right angled plane triangle.

§ *a*. Wherefore, if the figure which furnishes such proportions, be considered as a plane triangle, it will be right angled; the latitude will be one of its acute angles; the diff. long., the hypothenuse; and the dep. will be one of the legs of such triangle.

§ *b*. The result obtained from calculations conducted upon such principles, (§ 549.) must be only an approximation.



§ 586. Suppose a ship sailed E. 15½ miles on the parallel of 56° 15′ south latitude, her departure would be 15½ miles = the distance sailed.

§ *a*. And in the right angled triangle A B C, the angle A = 56° 15′, (the lat.); the leg A B = 15½. (the dep.); and the hypothenuse (§ 585. § *a*.) is the diff. long.

§ *b*. Now, if the diff. long. be made radius, of the arc C E, C B becomes it sine, and A B its co-sine, whence (§ 75.) arise the proportions, as under § 584.

FORMULÆ.

§ *c*. Rad. : diff. long. : : cos. lat. : dep.

§ *d*. Diff. long. : rad. : : dep. : cos. lat.

§ *e*. Cos. lat. : dep. : : rad. : diff. long.

§ *f*. *To find the corresponding diff. by calculation*, (§ *e*.)

Lat. 56° 15′ sec. = 0.255261 (§ 101. § *b*.)

Dep. 15.5 log. = 1.190332

Log. diff. long. = 1.445593 = 27.9 minutes (′)

§ 587. If the dep. (A B) be made radius to the arc B H, then the diff. long. becomes secant to the lat., and we have (§ 75. § *c*.):

§ *a*. Rad. : dep. : : sec. lat. : diff. long.

§ *b*. Sec. lat. : diff. long. : : rad. : dep.

§ *c*. Dep. : rad. : : diff. long. : sec. lat.

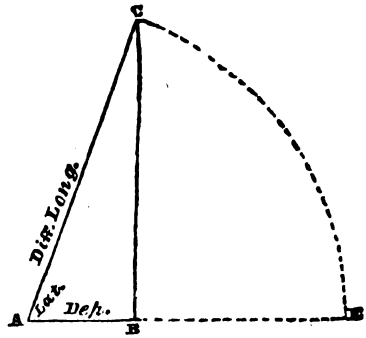
§ 588. Now, if the other leg (C B) be made radius, the dep. becomes co-tang. (§ 57. § *b*.), and the diff. long. the co-sec., of the latitude, whence (§ 75.) arise the following sets of proportions.

§ *a*. Co-tang. lat. : dep. : : co-sec. lat. : diff. long.

§ *b*. Co-sec. lat. : diff. long. : : co-tang. lat. : dep.

§ 589. To find the number of miles, or the dep., which correspond to 1° or 60′ on the parallel of 67° 30′.

Digitized by Google



§ *a*. The diff. long. being made radius, we have, (§ 586. § *c*.),
Rad. : diff. long. : : cos. lat. : dep.

Diff. long. 60 log. = 1.778151
Lat. 67° 30′ cos. = 9.582840

Log. dep. = 1.360991 = 22.9

§ 590. C (§ 32. § *d*.) is the complement of A, and is equal to 22° 30′. C B is the cos. of C, and shows the number of miles contained in 1° of long. on the parallel of lat. 22° 30′.

§ *a*. Diff. long. 60 log. = 1.778151 (§ 589. § *a*.)
Lat. 22° 30′ cos. = 9.965615

Log. dep. = 1.743766 = 55.4 miles,

which is equal to 1° of long. in lat. 22° 30′.

§ *b*. Now (§ 75. § *b*.) C B : cos. C : : A B : cos. A. A B shows the number of miles equal to 1° of long. in lat. 67° 30′, and C B shows the number of miles, that make 1° of long. in lat. 22° 30′, the complement of 67° 30′.

§ *c*. Wherefore, (§ 76.) in any lat., the miles in a degree of long. are to the cos. of that lat. as the miles contained by a deg. of long. in any other lat., are to the cos. of this lat. And conversely.

§ 591. As a right angled plane triangle (§ 585.) is involved in the solution of the several problems under § 586. § 587. § 588., etc.; the solution of every one of such problems may be obtained by means of the diagram. Plate 1.

§ *a*. The diff. long. (§ 585. § *a*.) is the hypothenuse; and the leg adjacent to the angle which in degrees (°), is equal to the latitude in which the dep. or diff. long. is made, is the dep.

§ 592. Of dep., diff. long. and lat., either is determined on the diagram, by means of the two others, in the same manner that any one of the three quantities, viz., diff. lat., dist. and course, is determined (§ 556. § *a*.) by means of any two of these.

§ 593. When the latitude in which the diff. long. or dep. is made, is

Digitized by Google

Plate 1. { less than 45°, the degrees of lat. are to be found on the *inside* of the graduated arc; and the dep. on the *base*.

§ *a*. But when the latitude is *greater* than 45°, the degrees of it are to be found on the *outside*, and the dep. on the graduated *arc*.

§ *b*. Thus, 26′ of long. is equal to 24.5 miles, in lat. 19°; and in lat. 71°, it is equal to 8.4 miles.

§ *c*. The *perpendicular* from the mark for the 19°th on the 26th arc, cuts the *base* at 24.5, which shows the dep. for 26′ of long. in lat. 19°.

§ *d*. The parallel from 71° on the 26th arc, cuts the graduated arc at 8.4, which is the dep. (§ 593. § *a*.) for 26′ of long. in lat. 71°.

EXAMPLES.

§ 594. A ship in lat. 27°, makes 20.5 miles dep. To find the diff. long.

§ *a*. The diff. lat. is found on the *inside* (§ 593.) of the graduated arc, and the dep. on the *base*.

§ *b*. The *perpendicular* from 20.5 on the *base*, intersects 27° on the 23d arc, then 23′ is the required diff. long.

§ 595. A ship in lat. 60°, makes 12 miles dep. To find the diff. long.

§ *a*. The degrees of the lat. (§ 593. § *a*.) are found on the *outside*, and the dep. on the graduated arc.

§ *b*. The parallel from 12, intersects 60° on the 24th arc; 24′ is the diff. long.

§ 596. The diff. long. between two places in lat. 33° is 27′. To find the dist. between them.

§ *a*. The lat. is found on the *inside* (§ 593.) of the graduated arc, and the dep. on the *base*.

§ *b*. The *perpendicular* from 33° on the 27th arc, falls upon the *base* at 22.6, the dist. in miles between the two places.

§ 597. The diff. long. between two places in lat. 54° is 24′. To find the dist. between them.

§ *a*. The degrees of lat. are on the *outside*, and the dist. (§ 593. § *a*.) is to be found on the graduated arc.

§ *b*. The parallel from 54° on the 24th arc, cuts the graduated arc at 14.1, the dist. required.

§ 598. The dep. between two places on the same parallel, is 18.4 miles, and the diff. long. is 20′. To find their lat.

§ *a*. The *perpendicular* from 18.4 cuts the 20th arc at 23°, the lat. required.

§ *b*. The dep. being found on the *base*, the degrees (§ 593. § *a*.) are taken from the *inside* of the arc.

§ *c*. But if the dep. were found on the graduated arc, then the degrees on the *outside* of the arc would show the lat.

§ 599. The diff. long. being 20′, and the dep. between two places in the same latitude being 6.8 miles; to find their lat.

§ *a*. The parallel from 7.8, cuts the 20th arc at 67°, which (§ 598. § *c*.) is the lat.

§ *b*. When the minutes (′) of long. exceed 30′, every division on the several graduated scales, (§ 566.) must be counted as a mile, or as a minute (′).

Digitized by Google

§ *c.* And when the minutes (′) of long. do not exceed 3′, the divisions on the graduated scales (§ 563.) must be decimated.

§ 600. Of the diff. long., dep. and lat., either one may be found, the others being given, by means of Table V.

§ *a.* The degrees at the top of the table, are those which are *inside* of the arc; and those at the bottom of the table, and on the *outside* of the arc, are the same.

§ *b.* The numbers in the column marked (dist.) stand for minutes (′) of longitude; they show the value of the hypothenuse of a triangle, whose legs are equal to the quantities in the next two columns; and whose acute angles contain, one the degrees at the *top*, and the other those at the *bottom* of the page.

Table V.

§ *c.* When the lat. is found at the top of the page, the miles which are equal to any number of minutes of longitude, are opposite to them in the column marked, at the top, (d. lat.)

§ *d.* Thus, in lat. 41° 60′ of long. = 45.3 miles.

§ *e.* If the degrees of lat. be found at the bottom of the page, then the miles which are equal to any number of minutes (′) of long., are found opposite to them in the column marked (d. lat.), at the bottom.

§ *f.* Thus, in lat. 71° 60′ of long. = 19.5 miles.

§ 601. When a ship sails due east, or west, she sails either upon a parallel of lat., or upon the equator, and the whole distance sailed is dep.; which may be converted into diff. long. by the formula § *f.* (§ 586.), or by means of the diagram (Plate I.), or Table V.; either of the two latter means is most convenient in practice.

§ 602. When a ship sails due north or south, she sails upon the arc of a meridian, and the whole distance sailed is diff. lat.

§ 603. It is frequently the case, that a ship sails during the day, on more courses than one, making a zigzag track.

§ *a.* In such cases, it would be a very tedious operation, after finding the diff. lat. and dep. for every course and distance, to convert the dep. for every such course and dist. into diff. long. by a separate operation.

§ *b.* Such circuity is avoided by taking the whole amount of dep., and converting it into diff. long. by a single inspection of the diagram, or of Table V.

§ 604. Suppose a ship sails from lat. 64° N., 216 miles N. E. by N.; she makes 120 miles of dep. and 179.6, say 180 miles or 3° diff. lat.

§ *a.* Now this dep. or the diff. long. is not all made upon the parallel of 64°, ′5°, ′6°, or ′7°; or upon any one of the intermediate parallels, but upon all of them together.

§ *b.* And in order to convert, by a single operation, this dep. into long., and to find the diff. long. which the ship has made by sailing this course and distance, the whole dep. is supposed to be made upon that parallel (65° 30′) which is midway between the lat. left (64°), and that (67°) arrived at.

§ *c.* This lat. (65° 30′) is called the *middle latitude;* it is *half the diff. lat. added to the latitude* left; or to that arrived at, if the latter be the less lat.

§ 605. If the number of miles in a degree of long. on the different

Digitized by Google

parallels, as you approach the poles, decreased, as the miles from the equator to those parallels increase, this method would show the true diff. long.

§ *a.* But the number of miles in a degree of long. at different parallels, is (§ 590. § *c.*) as the co-sines of the lat. of such parallels.

§ *b.* Wherefore, the result given by this method is only an approximate one.

§ *c.* But in working up "dead reckoning," "days' works," etc., this method is generally used; it is used in all cases, except in the computation of great distances.

§ 606. On ship-board, at the expiration of every hour, sometimes of every two hours, the course and distance sailed during that time are marked opposite each other, on the *log slate.*

Traverse Table.

§ *a.* And at the noon of every day, the courses and distances sailed in the preceding 24 hours are "taken off," for the purpose of "working up;" and the whole distance sailed on every separate course is set down, opposite to that course, in a *traverse table.*

§ *b.* The diff. lat. and the dep. for every course and dist. are taken, either from the diagram (Plate 1.) or from Table IV., and set down opposite to their proper course and dist. in the "traverse table."

§ *c.* The dep. and diff. lat. for every course and dist. are then added up; the sums show the whole dep. and diff. lat.

§ *d.* And by means of the whole dep. and diff. lat., the course and dist. "made good," are found on the diagram (§ 577. § *a.*), or are taken from Table IV. or V.

§ *e.* The "middle lat." (§ 604. § *c.*) is then found; and by means of it and the dep., the diff. long. is found (§ 594.) on the diagram, or in Table V.

Fig. A.

Course.	Dist.	Diff. Lat.		Depart.	
		N.	S.	E.	W.
N. by E.	20	19.6	- -	3.9	- -
S. W.	12	- -	8.5	- -	8.5

§ 607. Fig. A is the formula of a "traverse table."

§ *a.* The diff. lat. is written in the column marked N. or S. according as the course has *northing*, or *southing* in it. Thus, the diff. lat. for 20 miles N. by E. is put in the N. column, and the diff. lat. for 12 miles S. W. is written in the S. column.

§ *b.* The dep. must be placed in the column E. or W., according as the course has *easting*, or *westing* in it. Thus the dep. for the dist., 20 N. by E., is written in the E. column, and the dep. for the dist. 12, S. W. is written in the W. column.

§ 608. The dep. and diff. lat. for any dist. less than 300 miles, and for any course, are found in Table IV., in a manner similar to that by which they are found on the diagram.

§ *a.* If the course be less than 4 Points, it is to be found at the top

Digitized by Google

of the page, and the diff. lat. must be taken from the column marked at the top (d. lat.), and over which the course is found.

§ *b*. Thus, to take from Table IV. the dep. and diff. lat. for 120 miles S. ½ E.; find S. ½ E. at the top of the page, and 120 in the dist. column; then in the two columns, at the head of which S. ½ E. is found, and opposite to 120, are the diff. lat. 119.4, and the dep. 11.8.

§ *c*. But if the course be more than 4 Points, it is to be found at the bottom of the page, and the precept at the foot of the column must be the guide for taking out dep. and diff. lat.

§ *d*. Thus to take from Table IV. the dep. and diff. lat. for 30 miles E. N. E.; find E. N. E. at the bottom of the page, and 30 in the dist. column, then in the two columns, at the foot of which E. N. E. is found, are 27.7 (dep.) and 11.5 (diff. lat.) opposite to 30.

§ *e*. If the dist. exceed 300 miles, some aliquot part of it is taken as the 2d, 3d, etc., and the dep. and diff. lat. opposite to this quotient being increased by 2, 3, etc., as much as the dist. was reduced, give the required dep. and diff. lat. Thus to find the dep. and diff. lat. for 400 miles N. N. W.; take 200, the half of it; then, under N. N. W. and opposite 200, stands 184.8 in the d. lat. column, and 76.5 in the dep. do.; each of which being multiplied by 2, gives the required diff. lat. 369.6 or 6° 9′ 36″, and the dep. 153 miles.

§ *f*. Table V. is used in the same way for finding dep., diff. lat., etc., when the course is given in degrees. Thus the dep. for 18 miles N. 30° E. is 9 miles; and the diff. lat. for 40 miles S. 74° E. is 11 miles.

Variation 1 Point E.

Digitized by Google

§ 609. The courses in the first column of the "traverse table" are the courses sailed per compass.

§ *a*. Those in the second column are those corrected (§ 298. § *b*.) for variation, which is 1 Point E.

§ *b*. The diff. lat. and dep. in their columns, answer to the dist. and *corrected courses* to which they are opposite.

§ *d*. The diff. lat. 27′ .4 S. and the dep. 24.1 E. show that the ship, by sailing the several courses and distances in the table, went to the Southward and Eastward.

§ *d*. The dep. 24.1 and diff. lat. 27.4 are found opposite 36 (Table V.) and *under* 42°, which shows the course and dist. "made good," (§ 606. § *d*.) to be S. 42° E., 36 miles.

§ *e*. Under 41° (Table V.) 24.1 in the d. lat. column, stands opposite to 32 in the dist. column; the diff. long. then is 32′ East.

THE LOG BOOK.

The subjoined extracts are sufficient to show how the "log" is kept on board vessels in the navy. They are kept in the same way on board merchantmen, except that the log is hove only once in two hours.

MANNER OF KEEPING THE LOG.

U. S. Ship Saratoga, Josiah Tattnall, Esq., Commander. Off the Battery, New York, Monday, June 5th, 1843.

Commences with moderate breezes from the Sd. and Ed., and cloudy. Hoisted in the 2d cutter and cleared hawse. Transferred to the North Carolina Patrick McGann (sea). Rec'd on board 4 bbls. lime, 50 12 pd. shot, and 8 spare trucks.
B. S. B. Darlington.

From 4 to 8 moderate breezes from the Sd. and Ed., and thick hazy weather. At sunset sent down top-gallant yards. Got up the messenger—making preparations for sea.
B. S. B. Darlington.

From 8 to midnight light airs from Sd. and Ed., and light clouds.
E. C. Parrott.

From midnight to 4 light airs from the Sd. and Ed., and pleasant.
Chas. Heywood.

From 4 to 8 light airs, and pleasant. At 5 crossed top-gallant yards and cleared hawse; at 5.30 hove up the larboard anchor. Steamer Hercules came alongside and made fast. At 6 hove up the starboard anchor and commenced towing out of the harbour.
B. S. B. Darlington.

From 8 to meridian light breezes from the Sd. and Ed., and pleasant. At half past 10 cast off from the steamboat and let go the larboard anchor; sent a boat for sand. At meridian hoisted the broad pennant of Commodore M. C. Perry, and fired a salute of 13 guns.
E. G. Parrott.

Bearings per compass.—Sandy Hook Light E. by S.
" " Neversink Light S. E. by S.

After getting both anchors on the bows, the ship's draft was 16 ft. 8 in. forward.
16 ft. 4 in. aft.

Water expended, 260 Galls.
Wood, 40 Sticks.
Sick, 45.

GEORGE WELLS, *Acting Master.*

* H. for hours; K. for knots, or miles; F. for fathoms, or 8ths of a mile.

Commences with moderate breezes from the westward, and pleasant. At half past 1 hove up the anchor and stood out over the bar under all sail. At half past 2 the wind shifted to the Sd. At 3 o'clock passed the bar. At 3. 45 hove to and discharged the pilot, secured the anchors, and made all snug for sea. At 4 Sandy Hook Light bore N. ½ W., distant about 6 miles.

CHAS. HEYWOOD.

From 4 to 6 fresh breezes and pleasant weather. At 5. 30 furled top gallant sails. Several sails in sight. CHAS. S. BOGGS.

From 6 to 8 fresh breezes and hazy. At 7 inspected the crew at quarters. Loaded Nos. 8 and 9 guns with a round shot, and No. 7 with a Paixhan shell. At 8 called all hands and single reefed the main; double reefed the fore and mizen; unbent the cables and paid them below.

B. S. B. DARLINGTON.

From 8 to midnight strong breezes and light clouds, with haze and lightning to the Nd. and Wd. Commencement of the watch, ship labouring in her hull; moved further aft shot and other articles which had been stowed forward on the berth deck. At 9 brailed up the spanker. At 9. 30 hauled down the jib and hoisted F. T. staysail—hauled up the mainsail. End of the watch the ship easy. E. G. PARROTT.

From midnight to 4 fresh breezes and hazy weather. CHAS. HEYWOOD.

From 4 to 8 fresh breezes from the Sd. and Wd. Turned the reefs out of the top-sails, set top gall't sails and mainsail and starb'd top mast studding sail; set up the jib stay. CHAS. S. BOGGS.

From 8 to meridian fresh breezes and pleasant. At 9 sent aloft and crossed royal yards, set the sails and flying jib. At 10 set the starboard lower and fore and main top gall't studding sails. At 10. 30 took in the mizen royal and lower steering sail.

B. S. B. DARLINGTON.

GEORGE WELLS, *Acting Master.*

MERCATOR'S SAILING.

§ 611. Dep. : rad. : : diff. long. : sec. lat. (§ 587. § *c*.). Upon the principles involved in this proportion, the charts, called Mercator's, are constructed.

§ *a*. In these charts, the meridians of longitude, after they cross the equator, instead of approaching each other, till they reach the parallel

Digitized by Google

of any latitude, in the ratio (§ 486. § *b.*) of rad. to the cos. of that lat. are drawn parallel to each other.

§ *b.* And the parallels of lat., say at 1° a part, instead of being at equal distances from each other, are drawn in the ratio of rad. to the sec. of their latitude: by this means, places on a sphere are represented on a plane with their proper relative bearings.

§ 612. In this manner of representing portions of the surface of a sphere upon planes, the parallels of latitude are lengthened out, and the meridians of longitude are expanded.

§ *a.* So that, if the 1st degree of lat., from the equator, be divided on the chart into 60 equal parts, every degree as they succeed each other in numerical order, will contain a greater number of these parts than the 1st, or than that which precedes it; thus the 61°st of lat. contains 126 of these parts, and the 31°st, 70 of the same parts.

§ 613. These parts are called *meridional* parts.

§ *a.* Table VI. shows the number of meridional parts from the equator to any degree and minute within the parallel of the 84°th of lat. sec. lat. × 1.778151 (the log. of 60 miles) gives (§ 130. § *b.*) the meridional of parts for such lat. Upon this principle Table VI. is calculated.

§ *b.* The number of meridional parts between any two parallels, is called the *meridional* diff. lat. of those parallels.

§ *c.* Thus, the mer. diff. lat. between 13° 10′, and 18° 10′, is 312.

The mer. parts of 18° 10′ = 1109
do. 13° 10′ = 797
Mer. diff. lat. = 312
} Table VI.

§ 614. Now, if any section of the earth's surface be represented on a plane projected according to Mercator's plan, the *true* (nearly), instead (§ 550.) of the *approximate*, distance, etc., between any two places, may be determined by *plane* trigonometrical operations.

§ *a.* To do this, the Mer. diff. lat., as well as the actual diff. lat. between places, must be used.

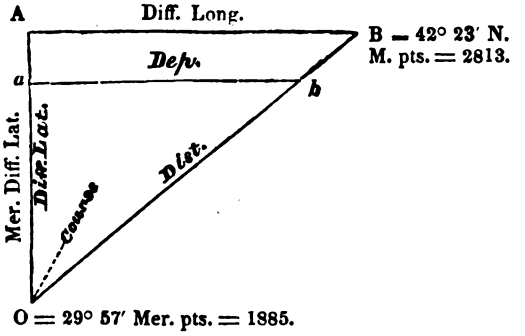
§ 615. Mercator's sailing is useful to the navigator, chiefly in enabling him to find, by plane trigonometrical calculations, the number of miles between places that are at a great distance from each other.

§ *a.* The several cases in loxodromic sailing, may also be accurately solved, according to the principles of Mercator's sailing; but the Mer. diff. lat. must be used, as well as the actual diff. lat.

§ *b.* Methods of applying the principles of Mercator's sailing to the solution of cases in loxodromic sailing, will be shown; but the application of them to practice will be left for the amusement of the learner.

Example. § 616. A B O represents the relative position of Boston and New Orleans in lat. and long., according to the principles of Mercator's sailing.

Digitized by Google



§ *a*. And the triangle *a b* O shows the bearing, dist., etc., according to loxodromic sailing.

§ *b*. The *meridional* lat. of Boston is 2813, and that of New Orleans is 1885, (Table VI.); and the difference between these (§ 613. § *b*.) is (O A) the Mer. diff. lat.; and A B is the diff. long.; A O B is the course from New Orleans to Boston.

§ *c*. According to the loxodromic plan of constructing the triangle, *a* O is the actual diff. lat. between the two places, and *a b* is the dep.

§ *d*. Whether the problem proposed be solved according to the loxodromic or Mercator plan, the actual diff. lat. between the two places is the same.

§ *e*. But the dep. and dist. determined by the former method (§ 550.) are not the true dep. and dist. between the two places.

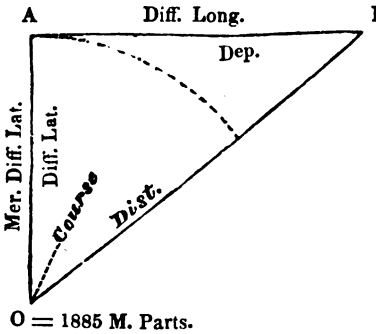
§ 617. As the angles *a b* O and A B O (§ 616. § *d*.) are equal, *a b* (§ 30. § *d*.) is parallel to A B; whence (§ 73. § *d*.) arise the relation between the sides of a triangle in loxodromic sailing when compared with the sides of a similar triangle in Mercator's sailing.

§ *a*. Diff. lat. : dep. : : Mer. diff. lat. : diff. long.; also inversely and alternately.

§ *b*. The relations between the other parts of the two triangles may be established according to the principles derived from § 72. and § 73. The learner may arrange them.

§ 618. If the Mer. diff. of lat. (O A) between New Orleans and Boston be made radius, several sets of proportions (§ 75.) will appear among the different parts of the triangle involved.

Digitized by Google



§ *a.* But the most useful proportion (and in fact almost the only one which occurs in practice), in Mercator's sailing, is that by which the *true* course and dist. between any two places are evolved. I shall give the terms of this proportion, and leave the others to be arranged by the learner.

§ 619. The Mer. diff. lat. (§ 618.) being radius; Mer. diff. lat. : rad. : : diff. long. : tang. course.

§ *a.* The diff. long. thus used, must in all cases be converted into minutes, which must be used in the log. Table of Numbers, as miles.

§ *b.* To find the course from New Orleans to Boston.

Boston	lat. 42° 23′	M. pts. =	2813
N. Orleans	" 29° 57′	"	1885
	12° 26′	"	
	60	"	928 = Mer. diff. lat.

Diff. lat. = 746 miles.

N. Orleans, long.	90° 9′ W.
Boston "	71° 4′ W.
	19° 5′
	60

Diff. long. = 1145 minutes (′).

Now, (§ 619.) 928 : rad. : : 1145 : tang. course.

928 log. (Ar. co.) = 7.032452
1145 log. (§ *b.*) = 3.058806

Tang. course = 0.091258 N. 50° 58′ 34″ E.

§ *c.* Then calling O A, the actual diff. lat., A B becomes dep., and retaining O A, as rad., we have (§ 574. § *d.*) rad. : diff. lat. : : sec. course : dist.

Digitized by Google

Diff. lat. 746 miles log. = 2.872739
Course N. 50° 58′ 34″ E. sec. = 0.200906

Log. dist. = 3.073645 = 1184.8 miles.

§ *d.* Problems in Mercator's sailing may also be solved either by Tables IV. and V., or by the diagram (Plate 1). Thus the mer. diff. lat., and the diff. long., being used on the diagram, or in the tables as diff. lat. and dep., show the course. Then with this course the dist. is found opposite to the actual diff. lat.

§ *e.* Philadelphia lat. 39° 57′ N. M. parts - 2619
Washington City lat. 38° 53′ N. " - 2536

1° 4′ M. diff. lat. = 83
60

Diff. lat. = 64 miles

Washington long. 77° 2′ W.
Philadelphia " 75° 9′ W.

1° 53′
60

Diff. long. = 113 minutes (′)

113 in the dep. column stands opposite to 83 in the d. lat. column; (Table V.) 54° is at the bottom of the page. The course then from Philadelphia to Washington is S. 54° W. On the same page 64 in the d. lat. column stands opposite to 109 miles, which is the dist. between the two places.

We give, in a note, the solution of a case in sailing, which will not be without interest to the *student* of navigation:*—(From the *American Journal of Science and Arts*, vol. xlvi. No. 1.)

* *Solution to a Case in Sailing:* By W. Chauvenet, A M., Professor of Mathematics, U. S. N.—In a late treatise upon navigation the following problem is solved by middle-latitude sailing, and the solution is accompanied with a note declaring that this case "cannot be solved by Mercator's sailing;"* and by referring to the various accessible works upon navigation I cannot find that any rigid solution has ever been printed, although it certainly cannot be regarded as difficult. The true solution may have been overlooked because it cannot be deduced by comparing the *similar triangles* employed in all popular works to illustrate Mercator's sailing; or it may have been neglected as unimportant because the case can seldom occur in practice. The problem, however, is not without interest, and a solution of it, theoretically accurate, though unnecessary to the advanced mathematician, may be acceptable to the student of navigation.

Problem.—"A ship sails in the N. W. quarter 248 miles (*d*) till her departure is 135 miles (*p*), and her difference of longitude 310 miles (D). Required her course (C), the latitude left and the latitude come to?"

GREAT CIRCLE SAILING.

§ 620. The shortest distance between any two places on the earth is not (§ 582. § *b.*) along the *Rhumb*, or line of bearing between the two

Solution.—By putting l = proper difference of latitude, P = meridional difference of latitude, we have immediately from the data

$$l = \sqrt{d^2 - p^2},\ \text{sin. C} = \frac{p}{d},\ \text{P} = \text{D co-tang. C},\ (1).$$

Now to find the two latitudes, represent them by $\text{L} + \frac{1}{2}l$ and $\text{L} - \frac{1}{2}l$, and let the meridional parts for these latitudes be A and A′. Then since an arc of Mercator's meridian from the equator to any latitude (the radius of the earth being 1) is equal to *the Naperian logarithm of the co-tangent of half the co-latitude*, we have

$$\text{A} = \text{Nap. log. co-tang. } \tfrac{1}{2}\,[90^\circ - (\text{L} + \tfrac{1}{2}l)]$$
$$\text{A}' = \text{Nap. log. co-tang. } \tfrac{1}{2}\,[90^\circ - (\text{L} - \tfrac{1}{2}l)]$$

which reduced to nautical miles by multiplying by the radius $\text{R} = \frac{360 \times 60}{2\pi} =$ 3437.7, and expressed in common logarithms by dividing by the modulus M = .43429, become

$$\text{A} = 7915.7 \text{ log. co-tang. } \tfrac{1}{2}\,(90^\circ - \text{L} - \tfrac{1}{2}l)$$
$$\text{A}' = 7915.7 \text{ log. co-tang. } \tfrac{1}{2}\,(90^\circ - \text{L} + \tfrac{1}{2}l)$$

From these we obtain

$$\text{A} - \text{A}' = \text{P} = 7915.7\ [\text{log. co-tang. } \tfrac{1}{2}\,(90^\circ - \text{L} - \tfrac{1}{2}l) - \text{log. co-tang. } \tfrac{1}{2}\,(90^\circ - \text{L} + \tfrac{1}{2}l)];$$

$$\frac{\text{P}}{7915.7} = \text{log.}\frac{\text{co-tang. } \tfrac{1}{2}\,(90^\circ - \text{L} - \tfrac{1}{2}l)}{\text{co-tang. } \tfrac{1}{2}\,(90^\circ - \text{L} + \tfrac{1}{2}l)} = \text{log.}\frac{\text{tang. } \tfrac{1}{2}\,(90^\circ - \text{L} + \tfrac{1}{2}l)}{\text{tang. } \tfrac{1}{2}\,(90^\circ - \text{L} - \tfrac{1}{2}l)}$$

and if $\frac{\text{P}}{7915.7} = \text{log. } n$, we have

$$n = \frac{\text{tang. } \tfrac{1}{2}\,(90^\circ - \text{L} + \tfrac{1}{2}l)}{\text{tang. } \tfrac{1}{2}\,(90^\circ - \text{L} - \tfrac{1}{2}l)} = \frac{\text{cos. L} + \text{sine } \tfrac{1}{2}l}{\text{cos. L} - \text{sine } \tfrac{1}{2}l};$$

from which we find $\text{cos. L} = \frac{n+1}{n-1}\,\text{sine } \tfrac{1}{2}l,$ (2).

To facilitate the computation by logarithms, put n = co-tang. ϕ, then $\frac{n+1}{n-1}$ = tang. $(45^\circ + \phi)$, and equation (2) becomes

$$\text{cos. L} = \text{tang. } (45^\circ + \phi)\ \text{sine } \tfrac{1}{2}l, \qquad (3),$$

which with the equation

$$\text{log. co-tang. } \phi = \frac{\text{P}}{7915.7} = \frac{\text{D co-tang. C}}{7915.7}, \qquad (4)$$

furnishes a very easy solution to the question.

In the example proposed we find by equations (1), C = 32° 59′, l = 208′. The computation of equations (4) and (3) will be as follows:

C = 32° 59′,	l. co-tang.	+ 0.18776
D = 310,	- - - -	+ 2.49136
Log. 7915.7,	- - - -	— 3.89849
Log. co-tang. φ = 0.06034,	- - - -	8.78063
ϕ = 41° 02′		
$45^\circ + \phi$ = 86° 02′,	- - -	l. tang. 1.15900
$\frac{1}{2}l$ = 104′	- - -	l. sine 8.48069
L = 64° 08′,	- - -	l. cos. 9.63969

$\text{L} + \frac{1}{2}l = 65^\circ\ 52'$, $\text{L} - \frac{1}{2}l = 62^\circ\ 24'$. The latitudes found by middle-latitude sailing, are 65° 55′, and 62° 27′.

U. S. Naval Asylum, Philadelphia, August, 1843.

Digitized by Google

places, but (§ 122. § *a.*) along the intercepted arc of that great circle which passes from one place to the other.

§ *a.* This principle, formerly of but little practical importance to the navigator when his course was governed altogether by the winds, has become of great importance since the introduction of steam in ocean navigation. As steamers are in a manner independent of the winds, and as the *shortest* distance is often practicable with them, we subjoin a problem in Great Circle Sailing especially for them.

§ 621. Suppose a steamer, bound from Sandy Hook to Liverpool, wishes to pursue the shortest rout, and therefore to sail on a Great Circle: To calculate and lay off on the chart the required arc of such great circle.

§ *a.* The lat. and long. of the two places are given; we therefore know the co-lat. of Sandy Hook and Liverpool, and the difference of longitude between them. Hence we have a problem under Case IV., (§ 200.,) in which two sides and their contained ángle are given, to find the third side, which is the shortest distance between the two places.

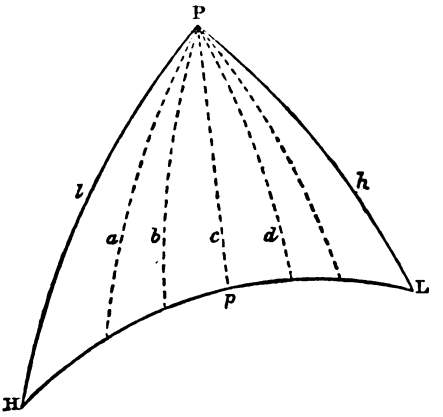
	Long.	Lat.	Co-lat.		
Sandy Hook	74° W.	40° 28	49° 32	= *l*	*Example.*
Liverpool	3° W.	53° 25′	36° 35	= *h*	

H P L	= 71° cos.	= 9.512642 (§ 200. § *l.*)	
h	= 36° 35′ tang.	= 9.870529 cos.	= 9.904711
Tang. aux. *a′*	13° 35′	= 9.383171 sec.	= 0.012321
l	= 49. 32		
(§ 200. § *m.*)	35. 57	- - - cos.	9.908233
§ *b.* Cos. *p* (dist. to Liverpool)	48° 2′	- -	= 9.825265
	60.		
Dist. in Naut. miles, -	2882 (§ 547.)		

§ 622. Having found the distance per Great Circle, the next step is to lay it off on the chart, so the vessel may sail by it. In order to do this, the co-lat. in which the Great Circle intersects the meridian of every fifth degree, or of every degree (as the navigator may determine) of longitude between New York and Liverpool, must be found by calculation.

§ *a.* The first step in this process is to find the angle which the Great Circle, thus found, makes with the meridian either of Sandy Hook or Liverpool, *i. e.*, either H or L (say H) of the original triangle, (p. 274.) The angles which *a* (the meridian of 70° W.), *b* (the merid. of 65°), *c* (the merid. of 60°), etc., make with *l*, successively form, with H and *l*, the three given parts of a triangle, from which the sides *a*, *b*, *c*, etc., or the co-lat. in which the great circle *p* crosses these meridians, are determinable.

Digitized by Google



§ 623. In the primitive triangle, p (§ 621. § b.) has been found, and H P L and h are given. Wherefore (§ 179.).

Sine H P L sine h. *co-sec.* p = sine H.

H P L	71°	sine	9.975670
h	36° 35′	sine	9.775240
p	48. 2.	co-sec.	0.128699
H =	49° 16′ 45″	sin.	9.879609

§ a. Now if we suppose a to represent the meridian of 70°, the angle H P a will be 4°, and the problem comes under Case III. (§ 199.), for H, l, and H P a, are the given parts.

H	49° 16′ 45″	tang.	= 0.065113	
l	49. 32	cos.	= 9.812248	cot. 9.930987
Cot. aux. A′ =	52° 59′	=	9.877361	sec. 0.220370
H P a	4			
	48° 59′	cos.	- -	9.817088
§ b.		Cot. a (co-lat.)	47° 5	9.968445

If, instead of taking out the *cot.* of the *co*-lat., the tang. of a had been taken out, we should have had at once the lat. in which the Great Circle crosses the meridian of 70° W.

§ 624. Now H, l, and aux. A′ are constant quantities for finding the value of the several sides b, c, d, etc. If, therefore, to the constant log. 0.151357 (cot. l and sec. A′) we add the cos. of the difference between A′ and the successive angles H P b, H P c, etc., we shall have *tang.* of the lat. in which these meridians cross the Great Circle p.

§ a. The sum or diff. of A′, and these angles, H P b, H P c, etc., must be used according to the precepts § j. and § k. (§ 199.)

Digitized by Google

Thus, to find where the Great Circle crosses the merid. of 65°: H P b = 9°.

	Constant log.	0.151357
H P b — A′ =	43° 59′ cos.	9.857056
Tang. lat.	45° 33′ =	0.008413

Therefore the Great Circle from New York to Liverpool crosses the meridian of 70° in 42° 55′ (§ 623. § b.); the meridian of 65°, in 45° 33′ etc.

§ 625. The Great Circle may be laid off more conveniently, but not so accurately, with the help of a common globe. For this purpose, stretch the brass quadrant from one place to the other between which a great circle is to be traced, and draw a slight pencil mark along the edge of the quadrant. Then bring the intersection of this pencil mark, or great circle with each meridian successively under the brazen meridian, to see in what lat. the intersection takes place. The lat. and long. of these intersections may be then transferred to the chart, and the vessel can then follow approximately the track thus indicated, by steering from one point of intersection to another. And for this reason, the *primary* points should not be taken more than a few degrees apart.

MERCATOR'S CHART.

§ 620. Nearly 300 years ago, Mercator, a Flemish geographer, constructed and published a chart according to the principles laid down under art. § 130. This chart distorts the appearance of the land, etc., but it preserves places in their bearings from each other, and is the chart used by navigators.

To construct a Mercator's chart.

§ a. Draw a line across the lower edge of the paper, as at Plate 7, (Sumner's method,) and divide it off upon the requisite scale, as 60 miles, for instance, or a degree of longitude to an inch; call this line the 1st parallel. Then upon this parallel erect a perpendicular, and take from Table VI. the meridional parts that are contained between the latitude in which it is intended this 1st parallel shall be, and the parallel of the next degree, and say, if 60 miles give one inch, how many inches and tenths of an inch will this meridional difference of lat. give? Then lay this distance off accordingly, on both the right and left margins of the paper. Do the same for every other degree, and draw the parallels of latitude through every 1°, 5°, 10°, etc. Then the lats. and longs. of head lands, prominent points and important places, can be laid down upon the chart, and the delineations of the intermediate coast line filled up by the eye with the requisite precision.

To mark the ship's place on the chart.

§ 621. Find, by means of a parallel ruler and a pair of dividers, the intersection of the parallel of her latitude with the meridian of her longitude; that point is the place of the ship.

To find the distance between two places on the chart.

§ a. If the two places be on the same meridian, the distance between

Digitized by Google

them, referred to the scale on the right or left, shows the number of miles between them.

§ *b.* If the places be on the same parallel, i. e., E. and W. of each other, and *not far apart*, the distance between them, referred with a pair of dividers to the scale on the right or left, but with one leg as much *above* as the other is *below* this parallel, will show roughly the required distance.

§ *c.* If the two places be in any other direction except E. or W., or N. and S. of each other, mark, in pencil, the parallel of either of the two places; take their diff. lat. in miles, from the scale at the top or bottom of the chart, and lay a ruler across the two places. Then keeping the legs of the dividers north and south of each other, slide one leg along the parallel drawn in pencil, until the other leg touches the ruler. Mark the point at which it touches. Then the distance between this point and that place through which the pencil was drawn, applied to the scale at the top or bottom of the chart, shows the required distance.

SURVEYING.

§ 622. It cannot be expected that a work like this should enter fully into the details of a survey. There are various treatises upon the subject to which it is proper the practical surveyor should refer. All that this work proposes to do, is merely to allude to the principles upon which surveys are conducted, taking it for granted that as the student has followed the course here laid down, thus far, he will comprehend at a glance the mathematical principles upon which Hydrographic Surveys are usually conducted.

§ *a.* In conducting the survey of a coast, harbour, etc., the first object should be to ascertain the geographical position of some point connected with the survey, and the next to establish a *base* line.

§ *b.* The most advantageous location for the base line, must be determined by the surveyor himself; and in this, he should be governed by circumstances, such as the nature of the ground about the place to be surveyed, and the place itself.

§ *c.* A level piece of ground should be selected for the base line, and the line should terminate at points, whence some of the prominent headlands, etc., of the place (say a harbour) under survey can be seen.

§ 623. The length of the base line must be ascertained by actual measurement, and the direction in which it lies must be established by observations, and noted down.

§ *a.* Then, knowing the length of the base line, it serves as a given side of a triangle, either for determining the length of other lines, or for finding the distance between either end of it, and any point visible from each end of the base.

§ *b.* For if the bearing of such point be taken from each end of the base, a triangle may be formed, in which the angles and the base are known, wherefore (§ 106. § *a.*) the two sides are determinable.

§ *c.* It is usual to set up signals not only at each end of the base, but at every point along the survey—called *primary* points or stations—

Digitized by Google

Digitized by Google

Digitized by Google

whose position it is desirable to establish. These stations are connected with the base through a series of imaginary triangles. The angular distance of one station from another is measured with a sextant or theodolite.

§ 624. The figure in the annexed plate is the *profile* of a harbour, that is being surveyed. A B is the base line, A C B, A D B, etc., are triangles constructed upon it; the angles at A, B, C, D, etc., are measured with a sextant or a theodolite, and the length of the lines B D, B C, A C, etc., is determined by trigonometrical calculation, or projection with an instrument called a *protractor*. The principal triangles used, are represented by the broken lines A X, A D, etc. Plate 9.

§ *a*. So that triangles may be constructed from one line to another, until sufficient data are obtained for determining every point of the survey.

§ *b*. The line (X Y) of verification is determined, as to its length, both by trigonometrical calculation, and by measurement, in order to establish the accuracy of the survey.

§ *c*. The position of the prominent points C, D, E, F, etc., is determined to a greater degree of nicety in this way, than it can be by taking cross bearings, etc., and the intersection of lines.

§ 625. After the *triangulation* of the survey is completed, and the points C, D, E, F, etc., are laid down upon the chart to the requisite scale; the intermediate spaces, G L, L H, etc., of the shore, may be filled up by the eye, assisted with the Plane Table. A little practice will enable one to sketch in these intermediate spaces with all necessary accuracy.

§ *a*. The position though, of every prominent point, such as light houses, rocks, hills, castles, etc., should be carefully established.

§ *b*. In taking the angles, all the angles of every triangle should be measured whenever it can be done. This affords one means of detecting errors during the work of triangulating; for if the sum (§ 32.) of the three angles of a triangle be not 180° according to the measurement, an error is known to exist.

§ *c*. Also the sum of all the angles around the same point (§ 26.) should be 360°; and, the sum of all the angles which lie within any measured angle, should be equal (§ 24. § *d*.) to the whole angle.

§ 626. In sounding, the observers sometimes go in the boat or vessel, and sometimes remain on shore. If they remain on shore, three are stationed each with a sextant and a watch previously compared, at different but well-established points. When the sounding party terminates a line, suddenly changes water, or requires the position of the boat to be fixed for any purpose, a signal is made, and each observer on shore measures the angle between the boat and some fixed point, and notes his time. The noting of time serves when the parties come in, to show what angles were measured together.

§ *a*. When the observers go with the sounding party, they observe in connection, usually from right to left—the first takes the angle between A and B for instance, the second between B and C, and the third for verification between C and D, or perhaps C and A, thus completing

Digitized by Google

the round. The third angle is measured for verification. At night and in unfavourable weather for field operations, the work should be plotted up.

§ 627. In sounding, when two stations come in range, it should be entered on the book of soundings.

§ *a*. In running lines of soundings it is sometimes convenient—when pulling at a uniform rate—to note the time at every important change, either of the bottom (which should always be noted) or the depth, then divide the line off by the time, and lay down the soundings accordingly.

§ *b*. The surest way of making a straight course in the boat, is to bring two points on shore in the same line of bearing, when it can be done, and then pull for them, keeping them in that line. For instance, a boat at *a*, would pull in a straight line to E, if she kept a tree, or a steeple, or any object at *b*, in a line with E; then the soundings taken would all be on the line *a* E; and the position at *a* being determined, the length of *a* E is known, and the soundings may be laid down.

§ 628. The soundings should be given for low water; wherefore the time of the tide when the soundings are being taken, should be noted, in order to correct them for low water.

§ *a*. The corrections to be applied are obtained by the rate of the rise and fall of the tide, as established by actual observation.

DESCRIPTION OF NAUTICAL INSTRUMENTS.

THE LEADS.

For the purpose of sounding and ascertaining the depth of water, vessels are generally supplied with two leads, viz., the hand lead, and deep sea lead, the former weighing from 7 to 12 lbs., the latter 28, and sometimes 56 lbs.

Hand Lead and Line.

The hand lead is attached to a line about 25 fathoms long, marked with leather at 2 and 3 fathoms, a white rag at 5, red do. at 7, leather at 10 and 13, and a red rag at 17 fathoms.

The 3d, 5th, 7th, 10th, 13th, 15th, 17th, and 20th fathoms are called *marks;* the others, *deeps*. Thus when the leadsman has 9 faths., he calls out in the leadsman's song, "by—the—deep—nine." With 10 faths., the announcement is, "by—the—mark—10;" 9½ faths. are called "and a half nine;" 9¼, "quarter less 10," and so on. At a convenient distance from the lead, the hand line has a toggle seized on to it, by which the leadsman is enabled to swing the lead once or twice over his head, in order to cast it well forward when the ship is going quickly; but as the hand lead takes about 6 seconds to sink 10 faths., soundings with it when the ship is going fast cannot be obtained except in very shoal water.

The Deep Sea Lead.

The deep sea, like the hand lead, is conical in its shape. It has a place in the bottom to receive an *arming* of tallow or soap, the object of which is to bring up specimens as of sand, shells, mud, etc., to show the character of the bottom.

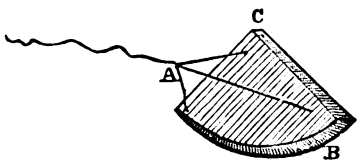
Stellwagen's Lead.

Lieut. Stellwagen has invented an ingenious contrivance, by which the trouble of *arming* the lead is avoided. It consists of an iron cup so fitted with a valve to the base of the lead, that on striking the bottom it will fill with specimens, and by the closing of the valve bring them up. It is called "Stellwagen's Lead."

THE LOG LINE.

The log line is attached to a flat piece of wood, B, called the *Chip*. The arched edge B is loaded with not quite lead enough to sink the

Digitized by Google



chip, so that when it is thrown into the water, the edge B will sink, while C will remain uppermost, so that the chip presents its flat side to the water, and thus resists the tendency of the line to drag it after the ship. It is toggled at A, so that, when hauled on, the toggle draws out, and the chip is then hauled in easily by one of the three legs of the line by which it is held.

The Chip.

Log Line. A rag is attached to the line at several fathoms from the chip; this length is called "stray line," and the use of it is to let the chip be clear of the eddy water under the counter, before you begin to count the knots.

From the rag, the line is divided off into lengths called knots, the distance between which bears the same proportion to a mile that the log glass does to an hour.

Log Glasses. The log glass is either a 14 or 28 second glass, called the "long" and the "short" glass. Now the number of feet in a knot is the same part of a mile that 28 seconds is of an hour. Thus there are 3600 seconds in an hour, and about 6080 feet in a nautical mile; and the proportion is—If a ship sail 6080 feet in 3600 seconds, or one mile in one hour, how far will she sail in 28*s*? Ans. 47 ft. +. Forty-seven—or rather 48, feet, therefore, is the length of a knot when the "long" glass is used. If two knots run out in 28*s*, the ship is sailing at the rate of two miles the hour; if four run out, she is sailing at the rate of four miles, etc. When going faster than this, the short glass is generally used; in which case half knots are counted as whole knots, and for obvious reasons.

THE MARINER'S COMPASS.

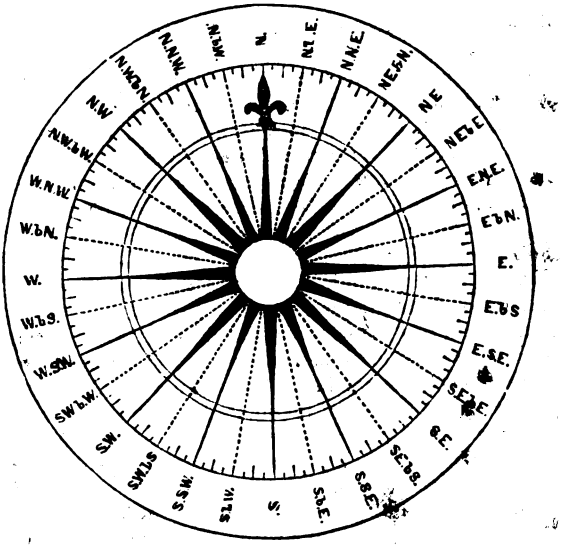
This is the most important but the most neglected of all nautical instruments. The figure annexed is a compass card, divided into 32 *points* of 11° 15′ each, which are again subdivided into half and quarter points. The N. S. E. and W. points, are called the *cardinal* points. The card is secured to the needle so that it turns about with the needle.

The needle is a steel bar which has an agate or ruby cap, nicely ground and centred, screwed in the middle of it. A steel or "composition" spindle rising up from the bottom of the compass *bowl* supports the card on its agate centre. The centre is made of agate and is thus supported on a hardened point, that there may be as little friction as possible, and that the card therefore may move freely.

The *bowl* is usually made of wood or brass. But it has been discovered that copper has a soothing, quieting effect upon the needle when disturbed; and that while it does not obstruct in the least the transmission of the magnetic fluid, it brings the needle quickly to rest when disturbed. Compass bowls therefore should be of copper.

The friction between the agate cap and the steel or composition point, though never so slight, will, in the course of time, wear both point and

Digitized by Google



cap away, and then the needle becomes sluggish, if not useless. To preserve the spare compasses, therefore, their needles should never be allowed to float except when the compasses are in actual use. The card should be lifted from its support, and the point protected from rust by sticking on it a bit of cork.

The north end, or *pole* of one needle repels the north pole of another, but attracts the south, *i. e.*, two north poles, or two south poles repel, but one north and one south attract each other. And the magnetism of a needle may be completely destroyed by bringing two north or two south poles together, though only for an instant. Therefore when the cards are lifted from their supports to be stowed away, they should be set on their edge, alternately, with the north pole of one pointing as the south pole of the other points.

When two steering compasses are used, they should be at least $2\frac{1}{2}$ feet apart, and so placed, that a line drawn parallel to the keel and through the centre of the card, may cut the *lubber's* point, which is a mark on the bowl by which the ship may be truly steered on a given course—only however when on an even keel; for it is obvious, the more the ship heels, the more will the *lubber's* point be inclined to this line.

THE AZIMUTH COMPASS.

The card of an azimuth compass is usually surrounded by a circle which is divided into degrees and halves, and sometimes to smaller divisions. The azimuth compass is falling into disuse very much in the merchant service; but it is of vast importance in navigation, and is

Digitized by Google

just beginning to be properly appreciated in the navy. There is reason to believe that many of the losses which are put down to the effect of "unknown currents" are owing to the circumstance that *proper* allowance is not made for the variation—local and other—of the compass.

The best azimuth compass now in use is the prismatic of Schmalcalder. It is mounted on a tripod something after the manner of a theodolite. It is furnished with a sliding mirror at one sight vane, and a prismatic eye-piece at the other, so that the divisions on the card may be read at the same instant that the thread in the sight vane is made to bisect the sun or its image.

In observing with the azimuth compass, the *stop*—which it ought never to have—*should never be used.* Instead of throwing the card out of centre with this contrivance and thus perpetuating error, a number of readings should be obtained in rapid succession, and the mean used as the correct observation. The tripod should be placed aft, as far as practicable from the surrounding iron—then, after shipping the compass in the socket, and spreading out the legs of the tripod, so that the compass may be level, a copper tack should be driven in the deck to mark the place of each foot of the tripod;—and by these marks, the azimuth compass should be placed whenever it is used. In this position, a line from the centre of the card should be drawn parallel to the keel, and the place where it cuts the bits or the bows, or the break of the forecastle forward should be marked, so that it can be seen from the compass, and used at any time as a *lubber's mark* for determining the heading of the ship by the azimuth compass; and this may be done with great nicety by looking at such lubber's mark through the sight vanes. As soon as the observation is finished, the card should be unshipped (to prevent centre and point from wearing), and put in the small box provided for it, not forgetting to protect the point by sticking a soft piece of cork on it, or wrapping it with fine tissue paper.

Local Attraction. In every ship there is an influence upon the needle called *local* attraction, which is exerted more or less, producing what is called *local deviation.* In men of war, steamers, and iron laden merchantmen, the local deviation amounts to several degrees. Without attending to the effects of this deviation, it is often impossible for vessels to make good the required course. Hence it is that those navigators who neglect this subject, find themselves compelled, even in the smoothest sea, and with the best helmsman, to bring in currents where no currents exist, to reconcile the diff. between their dead reckoning and observation. Hence it is, too, that two ships, though sailing in company, one under the stern of the other, seldom make their currents the same. They each allow the same variation, but each has a different degree of local attraction; and therefore what is ascribed to currents so generally, is oftentimes not the effect of currents, but of unreckoned local attraction.

There are in every ship two points of no local deviation. These points are when the ship's head is near north, or south. But for each ship they must be ascertained from actual observation. Indeed, the effect of local attraction, when the ship's head is on each of the 32

Digitized by Google

points of the compass, should be ascertained by experiment, and recorded for reference during the cruise.

For this purpose, after all the iron is in place on board ship, and the vessel is ready for sea, boats stowed, etc., the azimuth compass should be mounted on its tripod, the ship should be then slowly swung entirely around, and the bearings of some distant object—8 or 10 miles is far enough—noted as the ship's head is successively and *slowly* brought to the different points of the compass.

The effect of local attraction on the compass at each heading of the ship is shown in the annexed form—the object being 12 miles distant—and its true magnetic bearing, as ascertained from previous observations on shore, N. 33° E.

Ship's Head.	Bearing of object.	Local Variation.

W. N. W.	" 38 10 "	5 10 "
N. W. by W.	" 37 40 "	4 40 "
N. W.	" 37 "	4 "
N. W. by N.	" 36 10 "	3 10 "
N. N. W.	" 35 30 "	2 30 "
N. by W.	" 34 35 "	1 35 "

By this table it appears that the points of no local deviation are when the ship's head is about N. ¼ E. and S. ¼ W.

If a point cannot be seen so far off that the change in the position of

Digitized by Google

the ship in swinging around will make no appreciable difference in its bearings, then two compasses should be used, one being on shore. In this case the two compasses should be compared on shore, and their difference, if any, noted; with one of them on board, the ship should be then swung as before, and by a signal given from on board, as the ship comes slowly up to each point, the bearings of each compass noted from the other, while her head is on that point. From which observations a standard table, like the preceding, may be constructed for constant use at sea.

On account of the guns, anchors and other large quantities of iron about dock yards and near wharves, the table of local attraction should not be established until the ship has hauled off clear of their influence.

This table should be frequently verified at sea, by azimuths or amplitudes taken when the ship's head is on one of the points of no variation, and afterwards of greatest variation. If the difference of the two magnetic variations thus found, agree with the difference due the tabulated local variation, all's well. If not, a new table must be established (assuming the points of no local variation to be the same), by 32 azimuths, one taken while the ship's head is on each point of the compass. After crossing the equator a new table should always be established.

Azimuths should be taken as regularly as "sights" for latitude and chronometer. The difference between the ship's head per azimuth and steering compass should always be observed and logged. And in correcting the compass courses for dead reckoning, this difference should always be allowed for, in order to get the *true* courses steered. In entering the variation per observation in the log, it should always be first corrected for local deviation, so that the variations observed by one, being freed from the unequal effects in different vessels of local attraction, may appear the same to all. Take an example: A ship in the morning with her head N. ¼ E., (a supposed point of no local attraction,) finds the observed variation 5° 50′ E. She is becalmed, and in the evening when she heads W. by N., the observed variation is 11° 50′ E. Now if we refer to the Table, we shall see that there is a correction of 6° due for local attraction when the ship heads W. by N. The two observations therefore agree; and every other ship at this place, after correcting for her *local deviation*, will find the true variation 5° 50′ E. as recorded.

The observer should be careful, before he commences his observations, to lay aside from about his person every thing containing the least iron, such as knives, keys, watches, ever-pointed pencil cases, buckles about his stock and braces, boots with nails in the heels, and the like.

THE BAROMETER.

About 200 years ago a pump-maker, who was employed by the Duke of Florence to make a sucking-pump for a very deep well, discovered that notwithstanding his very great skill in his trade, he could not raise the water higher than about 32 feet from the bottom of the well. The fact was communicated to Gallileo, and an explanation asked. He talked about nature's abhorring a *vacuum* only to a certain extent; but he afterwards recommended the investigation of the subject to

Digitized by Google

Torricelli. Torricelli concluded that if it were the pressure of the atmosphere which raised the water 32 feet in a sucking pump, the same pressure ought to sustain a column of mercury about 30 inches, since mercury is 12 or 14 times heavier than water. Accordingly, he procured a glass tube about three feet long, and having hermetically sealed it at one end, he filled it with mercury; then placing his finger on the open end, he inverted it in a vessel of mercury. Removing his finger, he observed the column to fall until the top of it came within about 28 inches of the surface of what was in the basin. Holding the tube upright, the mercury remained in it, slightly oscillating. This is now known as the Torricellian experiment, and proved that the water in the pump and the mercury in the tube were upheld by the same weight. But philosophers were loth to admit that the atmosphere had weight; and at length it occurred to Pascal that if it were the weight of the superincumbent atmosphere which supported the mercurial column, that weight would be less on the top of a mountain, and consequently that there the mercurial column would not be as high as in the valley. He accordingly took two tubes filled with mercury, and inverted each in a basin of quicksilver at the foot of a mountain in Auvergne. The columns in each stood at the same height, or about 28 inches. Leaving a friend to watch one, he ascended the Puy de Dome with the other, and when he reached the top, observed the mercury to stand at about 24 inches, while the column in the tube left at the base of the mountain remained unaltered. This experiment was conclusive; and Pascal proposed the Barometer (Βαρος, *weight*, and μετρον, *measure*) for measuring the height of mountains by the weight or pressure of the atmosphere.

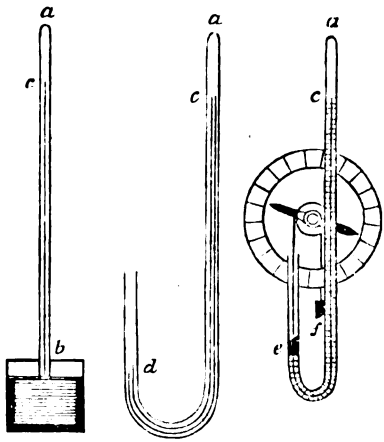
It was, however, soon discovered that the mercurial column, even at the same place, was continually subject to fluctuations. Hence, it was inferred that the atmospherical column was not always the same at any place. The changes in the Barometer, moreover, were observed to be most remarkable about the time of violent storms and other atmospherical disturbances. And hence the Barometer became to be considered an important meteorological instrument.

Fig. 1, (p. 288) is the *cistern* barometer, which is nothing more than Torricelli's inverted tube. The mercury should be pure; the tube about 34 inches long, and the hollow at least $\frac{1}{4}$ of an inch in diameter—near an inch is better, because then there is no capillary attraction. When ready to be filled, the tube and the mercury are heated, and the latter poured carefully in so as to exclude the atmosphere. With the finger on the end at *b*, it is then inverted, placed in the cistern and the finger removed; now the mercury descends from *a* to *c* until it is counterpoised by the atmosphere leaving the space *a c* nearly a perfect vacuum, or filled only with the vapours of mercury.

As the mercury descends in the tube it rises in the cistern, and as the height of the column is measured from the surface in the cistern, a correction on this account is necessary. Suppose the fall at *c* to be 9 times as great as the rise which it produces in the cistern. A fall of $\frac{9}{10}$ inches would therefore produce a rise of $\frac{1}{10}$ inches in the cistern —and the correction would be accordingly. But to avoid the trouble of calculating this correction, the best *land* barometers are generally

Digitized by Google

Fig. 1. Fig. 2. Fig. 3.



fitted with a contrivance for contracting or enlarging the cistern, so as to keep the surface of the mercury in it always at the same level. In some, as in Newman's barometer, the rod to which the scale is attached is provided with an adjustment by which its lower end may always be brought even with the top of the mercury in the cistern.

Fig. 2. Fig. 2 is the Siphon barometer, open at the short leg, as in the figure. The change of pressure which will alter the column one inch in Fig. 1, will only alter it in this $\frac{1}{2}$ an inch. Because when it falls $\frac{1}{2}$ an inch at *c* it rises $\frac{1}{2}$ an inch at *d*, and the weight of this $\frac{1}{2}$ inch at *d* balances $\frac{1}{2}$ an inch on the other side. In other words, *d* is a cistern, and a fall of $\frac{1}{2}$ an inch at *c* produces a rise to the same extent in the cistern.

Fig. 3 is a wheel barometer. When the mercury rises in the leg at *e*, it raises the weight, and the counterpoise at *f* descends, turning a hand or index over a plate having inches and parts marked on it, as the hours and minutes are on the face of a clock. Though barometers of this construction are frequently met with, they are, as philosophical instruments, of but little value.

There are barometers upon a variety of other plans, but they all depend upon the same principle.

The marine barometer is a cistern barometer. But in order to prevent the mercury from vibrating with the roll of the ship, it is slung in *gimbals*, and the lower part of the tube is very small, so that the mercury can pass between it and the cistern only through a very small orifice. The cistern is a buck-skin bag attached to a wooden cup.

Barometers are generally provided with an attached thermometer, that the correction for temperature may be applied.

As a general rule for this correction, "The ten thousandth part of the height of the column may be subtracted for every degree the attached therm. stands above 32°."

Digitized by Google

There is another correction: it is for capillary attraction in the tube, which attraction prevents the mercury from rising to its proper height, and causes the top of the column to present a convex appearance.

According to Mr. Ivory, the corrections for depression in tubes of different diameters, are as follows:

Diam. Tube. Inches.	Depression. Inches.	Diam. Inches.	Depression. Inches.
.10	.140	.40	.015
.15	.086	.45	.011
.20	.058	.50	.008
.25.	.041	.60	.004
.30.	.029	.70	.002
.35.	.021	.80	.001

Syphon barometers have both branches of the same diameter, and the depression is the same in each; and there is therefore no correction for depression in them.

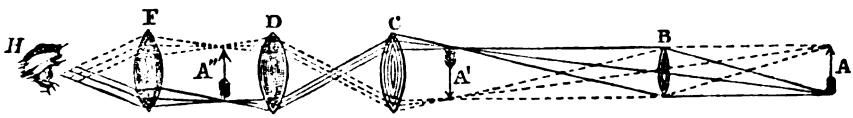
THE SYMPIESOMETER.

This is also an instrument for measuring atmospheric pressure. It may be best understood from an inspection of the instrument itself. The upper part of the tube contains hydrogen gas, which, being very elastic, compresses and expands according to the degree of atmospheric pressure upon the oil which is contained in a well or cistern, at the lower part. Hydrogen gas is readily affected by changes of temperature, or, in other words, it is very sensible to heat; consequently, the index by which the atmospheric pressure is read, must always be set according to the temperature, before an observation can be made.

SPY-GLASSES AND TELESCOPES.

Put a penny into an empty basin, and step back until the penny is just hid by the edge of the basin. Now pour in water, and the penny, without being moved, will appear in view. This is owing to the REFRACTION of LIGHT; and is in obedience to a law in optics, which asserts that rays of light, in passing obliquely through media of different densities, are always *refracted*, or turned out of the straight line in which they were proceeding. Upon this principle refracting telescopes, spy-glasses, and many other valuable instruments, are constructed.

B, C, D, F, are convex lenses. B is the object-glass of a telescope, and A the object to be viewed. The rays of light coming from A, are refracted by B, and crossing each other, form an inverted image at A', which image, thus inverted, may be viewed (magnified) through the

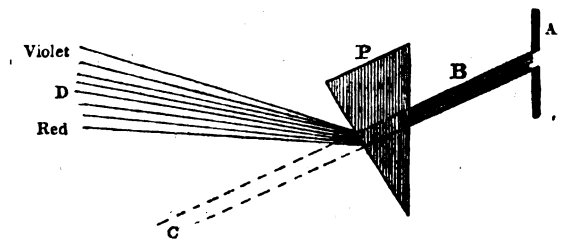


Digitized by Google

eye-glass C. This combination of lenses forms the Astronomical Refracting Telescope.

To fit this telescope for viewing terrestrial objects, which require to be seen erect, a tube, called the erecting eye-piece, containing two more lenses, D and F, is added. The first of them, D, forms an erect image in its principal focus at A″. The eye-glass F is then so placed that this image will be in its anterior focus, and the eye at H views it erect. This combination is the common spy-glass, or Naval Telescope.

In the foregoing description the light is considered as homogeneous, and every ray as having its angle of incidence and refraction equal. This, practically, is not the case. If a pencil of rays be admitted into a darkened room through a hole in the wall, as at A, so as to fall upon a glass prism P; instead of proceeding on in the straight line A C, they will be refracted in the direction D, and will form upon a screen at D, an oblong spectrum, in which are exhibited all the colours of the rain-

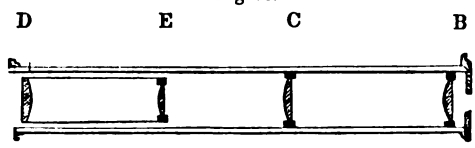


bow; the violet rays being the most refrangible will be highest up; and the red, being the least refrangible, will be the lowest down. Refraction through the lens B, (page 289,) is attended with precisely the same phenomenon, so that objects viewed through such a telescope as is there described, appear fringed with different colours, as purple, green, and the like. This was a great defect with the first telescopes. To do away with this chromatic effect of refracted light, and to render telescopes *achromatic*, was for a long time a great desideratum. After Newton had demonstrated the impossibility of accomplishing this desideratum, it occurred to Mr. Hall, and afterwards to Dollond, that telescopic images might be rendered free of prismatic colours by viewing objects through media of different forms and dispersive powers. It was proposed, therefore, that the object glass of the telescope should consist of two lenses instead of one; that the outer lens should be convex, and of *crown* glass—that with which our windows are glazed—and that the inner lens should be concave, and of flint glass—the focal distance of the two being to each other as 33 to 50, *nearly*. To this arrangement we are indebted for the beauty and perfection of our telescopes, whether astronomical or terrestrial.

The combination of lenses exhibited in Fig. A forms the erecting achromatic eye-piece now most in use. If the cell containing the two inner lenses be removed, an inverting telescope, like the "night-glass"

Digitized by Google

Fig. A.

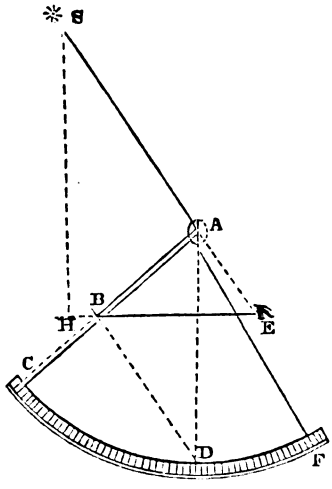


of seamen, may be formed of a common spy-glass. E and C are nearly plano-convex, D is a meniscus, B is double convex in the proportion of 1 to 24 between the sides.

The "night-glass" proper, usually has a larger object glass than the common "day-glass;" but only one lense is used for the object glass; it is not achromatic, and objects viewed with it by daylight appear inverted and fringed around with prismatic colours. The night-glass usually consists of but three lenses, viz., two for the eye-piece, and one for the object glass. *Night-glass.*

THE SEXTANT.

The Quadrant, the Sextant, and the Circle of Reflection, all depend upon the same principles in catoptrics, viz: if an object be reflected from two mirrors which are perpendicular to the same plane, the angular distance of the object from its image thus reflected will be double of the angle of inclination between the mirrors.



Thus, let A and B be two mirrors perpendicular to this page, but inclined to each other at the angle B D A: this angle of inclination will be half the angular distance of S from its image when seen in the horizon as at H.

If a ray of light, proceeding in the direction S E from a star at S, fall upon a mirror A, it will be reflected along the line A B towards C. But falling upon a second mirror at B, inclined to A at the angle B D A, it will be reflected back to the eye, so as to cross its first line of direction in E. Now in optics, the angle of incidence and reflection are always equal, wherefore B A D = D A E, and C B D = D B E. Consequently B A E = 2 B A D; and C B E = 2 C B D. Now (§ 31.) the exterior angle C B E = B A E + A E B. Also (§ 31.) C B D = B A D + B D A. But 2 C B D = C B E; therefore C B E is

Digitized by Google

also equal to 2 B A D + 2 B D A. Consequently B A E + A E B = 2 B A D + 2 B D A. But it has just been proved that B A E = 2 B A D. Eliminating these two terms, therefore, we have A E B = 2 B D A: Or the angular distance of an object at S, from its image at H, is double the angle of inclination between the mirrors by which the angle is measured.

In taking an altitude, etc., with a sextant, quadrant, or circle, it is this angle B D A, or the inclination of the mirrors to each other, which is really measured. And as this inclination is only half the angle which we wish to measure, the graduated arcs of these instruments are reckoned at twice their value. Thus, an arc of 30′ is counted as 60′. Hence it is that the arc of a quadrant measuring angles of 90°, is but really 45°, and the quadrant, instead of being a quarter of a circle, as its name indicates, is really but the eighth. So with the sextant which, measuring 120°, is really but an arc of 60°.

Now if we imagine the mirror A to be movable around a centre at A by means of a bar, as A D, page 291, the lower end of which moves on the graduated arc C F, so that by moving along this arc, and of course changing the angle of inclination between the mirrors at A and B, the image of a star at S may be brought to the horizon at H, we shall have in full, the principle upon which sextants and quadrants are constructed. It therefore only remains to explain the different parts of one of these instruments and the manner of adjusting them.

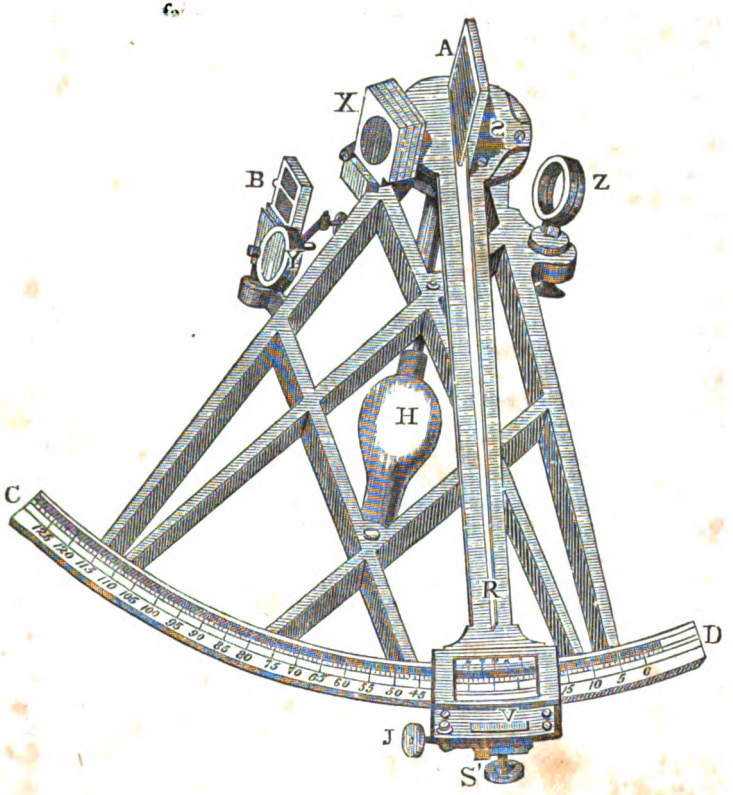
From what has been already said, it may readily be perceived, that the mirrors both at A and B should each be perpendicular to the plane of the instrument, and that there should be some guide for directing the eye at E in a line which is parallel to the plane of the instrument. These are the principal adjustments. The annexed figure (p. 293) is a drawing of the sextant. A is the index glass. B, the horizon glass, partly silvered so that objects may be seen through one part of it; X and Y are coloured glasses, or *screens*, which are interposed when the sun is too bright or when there is a glare about the horizon; or when from any cause it is desirable to soften the light. H is the handle. A R the radial or index bar which turns the index glass A on the centre of the instrument and carries a small scale V, called a *Vernier*, from the name of its inventor. If the arc C D be divided to 15′, angles to the value of 15″ may be read off by means of the subdivisions on the vernier at V, the vernier or zero mark of which should be exactly in the plane of the index glass at A, otherwise there may be an *index* error. S′ is a clamp and J a tangent screw for the purpose of giving slow, easy, and certain motion to the index-glass by means of the bar A R. Z is the sight vane, also used for holding the telescope.

THE ADJUSTMENTS.

To set the index-glass perpendicular to the plane of the instrument.

Move the vernier V, into the middle of the arc C D. Look obliquely in the index-glass—so that part of the arc C D may be seen both direct and by reflection. If the two parts appear in an unbroken curve, the

Digitized by Google



adjustment is complete; but if the reflected part appear too high up, or above the other, the index-glass inclines towards its face, and the screws at S must be screwed in; but if the reflected part be below the other, then the glass inclines backward and the proper screw must be turned the other way or loosened, till the two arcs appear as one. *The Index-glass.*

To set the horizon-glass perpendicular to the plane of the instrument.

Having adjusted the index-glass, hold the instrument perpendicular to the plane of the horizon—then move the index till the horizon as seen direct and by reflections appear in one unbroken curve. Now turn the instrument very obliquely to the plane of the horizon—nearly parallel to it—and if the two lines still appear as one, the adjustment is complete. This adjustment may be effected by the sun or a star. For this purpose screw the telescope into its socket at Z—adjust it for focus, screw on the dark eye-glass, or turn down the screens both at X *The horizon-glass.*

Digitized by Google

and Y—taking them of different colours so as to present contrast between the two images of the sun. Direct the telescope to the sun, and by means of the vernier at V, make the image pass to and fro above and below the sun. If one image can be made exactly to cover the other, the adjustment is complete. If not, the proper screws about B must be touched till the coincidence becomes complete. A bright star without the screens answers well for this purpose.

The telescope. There are, in the common focus of the telescope, two parallel wires, for the purpose of directing the eye of the observer to the centre of the field of view, or along the optical axis of the telescope, called the line of *collimation*, which line should be parallel to the plane of the instrument. To ex-

Adjustment of Collimation. amine whether the line of collimation be parallel to the plane of the sextant, measure the angular distance between two well-defined objects about 90° apart, viewing the contact, (the vernier being clamped,) first near one wire and then the other. If at each point of view the contact remain the same, the adjustment is complete. But if the images which touch at one wire overlap at the other, the optical axis of the telescope is not parallel to the plane of the instrument, and it must be made so by turning one and loosing the other of the two screws in the collar Z. A few trials will complete this adjustment.

The Index Error. When O on the vernier stands at O on the graduated arc C D, the index-glass and horizon-glass should be parallel to each other; if they be not parallel when the index is clamped at zero, any object, as the sun or a star, to which the line of sight of the instrument may be directed, will appear double, and the two images will appear farther apart, according as the two mirrors are more inclined to each other. This error may be corrected by turning the horizon-glass on its axis till the two images coincide. But it is generally better to ascertain the amount of this error, and use it as a constant correction to be applied to every observation. Thus, make the two images of the sun tangent to each other, alternately above and below, and read the distance at each time of tangent, of O of the vernier from O of the arc; half the diff. of these two distances when on opposite sides of zero of the scale, and half their sum when on the same side, will be the index error; and this error will be subtractive when the reading with the image *below* the sun is the greater, and additive when the contrary.

Examples.

	1*st.*	2*d.*
On (*i. e.*, image below)	— 31′ 45″	— 1° 2′ 15″
Off (*i. e.*, image above)	+ 31. 30	— 45″
	2)15	2)1. 3. 0″
Index error,	— 7″	— 31′ 30″

The Screens. It is important that the face of the coloured glasses should be exactly parallel; for if they be not, there will be an error, on account of refraction depending upon

Digitized by Google

the angle of the face and the inclination of the incident ray. There is no adjustment for this error; it must be ascertained by reversing the coloured glasses, and measuring the same angle with those glasses direct and reverse, and taking the mean of the two readings as the true angle to be measured.

THE ARTIFICIAL HORIZON.

The artificial horizon is a valuable companion of the sextant, inasmuch as it affords, whenever it can be used, the means of measuring altitudes more correctly than they can be measured from the natural or sea horizon. It is made by pouring molasses or mercury, generally the latter, into a basin or trough, which is so placed that the objects whose altitude is to be measured may be seen reflected in it. If a ray of light as from S, strike a plane reflecting surface H, truly parallel to the horizon, (as the surface of mercury in a basin,) an image of the object may be seen at S′ as much *below* the horizon as the object is above. If, therefore, the angular distance S E S′ between this object and its image in the artificial horizon be measured with a sextant A C B, it will be exactly double the angular distance, or alt. of the object above the natural horizon. This supposes that the angle S E S′ = S H S′. Their difference is E S H, which on account of the distance of the eye at E from the quicksilver at H, as compared with the distance of the sun and stars from the same points, is *immeasurably* small. This quantity therefore is neglected even in the nicest observations. The artificial horizon is provided with a cover, which consists of two plates of glass supported on a double-inclined plane. Its use is to protect the trough of mercury from the wind. Therefore when it is necessary to use the cover, it should be reversed after each altitude, in order to counteract the errors arising from unequal refraction through the glass plates.

TABLE XIX.

LATITUDES AND LONGITUDES OF PLACES ALPHABETICALLY ARRANGED.

1. N. E. Coast of British America.
2. United States.
3. West Indies.
4. E. Coast of America, from Mexico to Cape Horn.
5. W. Coast of America, from Cape Horn to Icy Cape.
6. Atlantic, Europe and adjacent Islands.
7. E. and S. Coasts of Mediterranean.
8. E. S. and W. Coasts of Africa.
9. Asia and adjacent Islands.
10. Polynesia and Pacific Ocean.

Digitized by Google

ABBREVIATIONS.

L.—Light.
R. L.—Revolving Light.
in. L.—Intermitting Light.
min.—Minutes of time of revolution of light.
sec.—Seconds " " "
m.—Miles of distance at which the light can be seen from deck.
I.—Island.
Is.—Islands.
Obs.—Observatory.
Cath.—Cathedral.
Fl. st.—Flag staff.
2 Ls.—Two lights.
Ho.—House.

Example.—Cape Elizabeth, 2 Ls., 1 R., 2 min., 25 m.,

Means Cape Elizabeth, two lights, one revolving in two minutes, can be seen twenty-five miles from deck of average height.

GENERAL INDEX.

ALGEBRA, Definitions, p. 19, § I; Addition, p. 20, § XX; Subtraction, p. 22, § XXIII; Multiplication, p. 22, § XXIV; Division, p. 24, § XXXII; Equations, p. 24, § XXXVIII; Proportions, p. 27, § XLV.

ALMANACK, THE NAUTICAL, p. 167, § 293.

ALTITUDES, of a Heavenly Body, p. 165, § 282; the complement of, § 282; Observed, § 283; Apparent, § 283, § 289; True, § 283, p. 166, § 290; Equation of Equal, p. 194, § 399; Reduction of Circum-meridian, Table XVI, p. 180.

AMPLITUDES, p. 175, § 324; Taking the, p. 177, § 337; Demonstration, p. 177, § 338; to find the, by Table VII, § 339.

ATTRACTION, LOCAL, p. 170, § 300.

AZIMUTHS, How to take, and find the Variation of the Compass, p. 173, § 320; The Magnetic, p. 171, § 304; The True, p. 171, § 310, p. 174, § 321; of a Celestial Body, pp. 166, 167, § 291; Circles of, pp. 164, 165, § 278, § 279, § 280.

BAROMETER, History of, p. 286; Description of, p. 287; Mariners, p. 288; Correction for, pp. 288, 289.

CHARTS, Mercator's, p. 270, § 620; to Construct a, p. 270, § 620; to mark the Ship's Place on a, p. 270, § 621; to find the Distance between two places on a, p. 270, § 621.

CHRONOMETER, Treatment of, p. 199, § 405; Longitude by, p. 189, § 390; Error of, p. 189, § 393; Rate of, p. 189, § 393; Rating of, p. 190, § 396; Rating of by Equal Altitudes, p. 192, § 397; By equal altitudes when the star is E. or W., p. 192, § 397; When the star is on opposite sides of the meridian, p. 193, § 398.

COMPASS, The Mariner's, pp. 282 and 283; The Azimuth, pp. 283 and 284; Local deviation of, p. 284; Variation of, p. 196, § 294.

DAY, Time of, p. 184, § 379; Astronomical, sea, or civil, p. 156, § 211; Sidereal, p. 156, § 212; Astronomical, p. 157, § 220; Civil, § 221.

DECIMALS, Definitions, p. 11, § 1; Addition and Subtraction of, p. 11, § 4; Multiplication and Division of, p. 13, § 6; Reduction of, p. 14, § 8.

Declination, Definition, p. 162, § 255; Circles of, p. 162, § 256; Parallels of, p. 162, § 257; Complement of, p. 162, § 258; Taking out Sun's dec., p. 167, § 293; Taking out Moon's, p. 168, § 293.

Dip of the Needle, p. 171, § 307.

Earth, Motion of, p 155, § 205; Revolution of, on axis, p. 156, § 209; Revolution of, in orbit, p. 156, § 210.

Ecliptic, p. 157, § 222; Signs of the, p. 157, § 224.

Equator, Poles of the, p. 159, § 233; Diameter of terrestrial, p. 159, § 235; Celestial equator, p. 159, § 236.

Equinox, Points of the, p. 158, § 225; Vernal, p. 158, § 226; Autumnal, p. 158, § 226; Precession of the, p. 158, § 228.

Geometry. Part I.—Definitions, p. 31, § 1; Axioms, p. 35, § 24; Propositions, p. 35, § 25.
Part II.—Definitions, p. 49, § 49, p. 54, § 64; Propositions, p. 51, § 59, p. 55, § 70; Axioms, p. 55, § 69.

Glasses, Spy, p. 289; Log, p. 282.

Horizon, Cardinal Points of, p. 163, § 272; Sensible, p. 163, § 274; Rational, p. 164, § 275; Poles of the Rational, p. 164, § 275; Zenith, p. 164, § 276; Nadir, p. 164, § 277; Secondaries to the, p. 164, § 278; Artificial, p. 295.

Horary Angle, Valve of, p. 178, § 346; Time and Degrees, p. 179, § 346; Definition, p. 163, § 262.

Latitude, Definition, p. 161, § 247; Parallels of, p. 161, § 249; by Meridian Altitudes, p. 199, § 406; by Circum-meridian Altitudes, p. 200, § 409; by Double Altitudes, p. 204, § 414; Correcting for Distance Sailed, p. 207, § 421; Formula for Finding the Lat. at Sea by Double Altitudes, the Mean Declination being used, p. 208, § 430; by two Planets at the same time, p. 210, § 434; by two objects at different times, p. 212, § 442; Sumner's Method, p. 216, § 459; Line of Position, p. 218, § 462; Littrow's Method, p. 222, § 467; by Lunars, p. 229, § 493; by the North Star, p. 237, § 515; Diff. of, p. 162, § 254.

Lead, Hand Lead and Line, Deep Sea, Stellwagen's, p. 281.

Light, Motion of, p. 183, § 376.

Log, The Log Book, p. 262; Manner of keeping the Log, p. 262; Line and Chip, p. 281.

Logarithms, Definitions, p. 65, § 83; Index, p. 67, § 83; Mantissa, p. 67, § 83; To take out Logarithms of Numbers, p. 68, § 84; Logarithms of Mixed Numbers, p. 69, § 87; The Arithmetical Complement, p. 70, § 88; Logarithms of fractions, p. 70, § 90; Taking out natural numbers, p. 71, § 93; Multiplication by Logarithms, p. 73, § 94; Division, p. 73, § 95; Involution, p. 73, § 96; Evolution, p. 74, § 97; Logarithms of Sines, Tangents, Secants, &c., p. 74, § 98.

Longitude, Definition, p. 161, § 252; Diff. of, p. 162, § 254; By Chronometer, p. 189, § 390; Formula, p. 197, § 402; By Lunars, p. 227, § 484; Circles of, p. 161, § 250.

Digitized by Google

Lunars, Problem, p. 224, § 468; True lunar distance, p. 225, § 470; Observed, p. 225, § 471; Apparent, p. 225, § 472; Selection of a star, p. 229, § 490; Formula for Lat. and time of day by Lunar Observation, p. 232, § 506; Finding the true Lunar distance, p. 234, § 509; Improved method for finding the true from the Obs. Lunar distance, p. 236, § 514.

Meridians, Definition, p. 161, § 248; Prime Meridian, p. 161, § 252.

Moon, phases of, p. 182, § 360; Opposition, p. 182, § 361; Conjunction, p. 182, § 362; Light of, p. 182, § 363; Eclipse of, p. 183, § 366; Syzygies, p. 183, § 367; Quadrature, p. 183, § 369; Disc, p. 183, § 371; Digit, p. 183, § 372; Apogee, p. 183, § 373; Perigee, p. 183, § 374.

Navigation, p. 245, § 542; Course and Distance, Diff. of Long. and Lat., p. 245, § 544, Departure, p. 246, § 548; Formula for Day's Work, p. 265, § 610; Diagram, p. 247, § 551; Loxodromic Sailing, p. 251, § 572; of turning Departure into Diff. of Long., p. 255, § 581; Traverse Table, p. 260, § 606; Mercator's Sailing, p. 267, § 611; Great Circle Sailing, p. 272, § 620; Solution to a Case in Sailing, note, p. 271.

Nodes, p. 158, § 231; Ascending, p. 159, § 231; Descending, p. 159, § 231.

Parallax, p. 166, § 258; Horizontal, p. 166, § 287; in Altitude, p. 166, § 287.

Planets, Satellites, p. 181, § 355; Inferior Planets, p. 181, § 356; Superior, p. 181, § 357: Primary, p. 158, § 230; Telescopic, p. 158, § 230; Jupiter, p. 181, § 358.

Projection, Stereographic, p. 172, § 313; Primitive Circle, p. 172, § 314; Projecting Point, p. 172, § 314; Oblique Circles, p. 172, § 318; Right Circles, p. 173, § 318.

Refraction, Definition, p. 165, § 284.

Right Ascension, Definition, p. 162, § 260; how reckoned, p. 162, § 261.

Sextant, Description of, p. 291; Adjustments, p. 292; The Index and Horizon Glasses, p. 293; The Telescope, Index Error, Screens, p. 294.

Spherics, Definitions, p. 103, § 119; Right Angled Spherical Trigonometry, p. 108, § 154; Catholic Proposition, p. 109, § 154; The Circular parts, p. 109, § 154; Problems and Demonstrations, p. 110, § 155; Solution of cases, p. 122, § 168; Napier's Analogies, p. 135, § 183; Oblique Spherics, p. 140, § 192; Solution of cases, p. 141, § 197.

Sun, Sunrise and Sunset, p. 178, § 340.

Surveying, Establishment of base line, p. 276, § 622; Primary points or stations, p. 276, § 623; Line of verification, p. 277, § 624; Measuring angles, p. 277, § 625; Sounding, p. 277, § 626; Corrections for rise and fall of tide, p. 278, § 628.

Tables, Table I, Logarithms of Numbers, p. 3; Table II, Logs. of Sines, Tangents, Secants, &c., p. 23; Table III, Proportional Logs., p. 79; Table IV, Courses, Dist., Departure and Diff. Lat., p. 96; Table V, Dist., Diff. of Lat., Departure, p. 111; Table VI, Meridional parts, p. 159; Table VII, Amplitudes, p. 166; Table VIII, Time of Sun's rising and setting, p. 170; Table IX, Atmospherical Refraction, p. 174; Table X, Augmentation of Moon's semi-diameter, p. 174; Table XI, Parallax of the Sun in Altitude,

Digitized by Google

p. 174; Table XII, Logs. for Equation of Equal Altitudes, p. 174; Table XIII, Correction of Moon's App. Alt. for Par. and Mean Ref., p. 176; Table XIV, For converting mean into sidereal time, p. 178; Table XV, For converting sid. into mean time, p. 178; Table XVI, Reduction of Circum-meridian Altitudes, p. 180; Table XVII, Greatest time from noon at which Circum-meridian Altitudes should be taken at sea, p. 184; Table XIX, Maritime positions, p. 299; Table XX, Declination of the Sun and Equation of Time at Apparent Noon, Greenwich, for 1845, 1846, 1847 and 1848, p. 321.

TELESCOPES, Description of, p. 289; Refraction of Light, p. 290.

MAURY'S NAVIGATION.

AN ELEMENTARY, PRACTICAL, AND THEORETICAL TREATISE ON NAVIGATION: WITH A NEW AND EASY PLAN FOR FINDING DIFF. LAT., DEP., COURSE, AND DISTANCE BY PROJECTION. BY M. F MAURY, LIEUT., U. S. NAVY.

OPINIONS OF NAVIGATORS AND PROFESSORS.

BOSTON, April 21st, 1835.

A work of the kind you are preparing for the press, containing the demonstrations of the formulas of Nautical Astronomy, would be very useful to those who have a taste for the subject, and would like to examine the demonstrations of the rules.

Respectfully,
Your obedient servant,
N. BOWDITCH.

PHILADELPHIA, 14th April, 1835.

DEAR SIR:

I have examined, with as much care as the nature of my engagements has permitted, the book intended for the instruction of the younger officers of the navy, which you have left with me. My opinion is, that such a work will be valuable to them, and will meet with favour among them; supplying, as it does, the mathematical principles involved in the studies of their profession in a sufficiently condensed form.

Coming from one of their own profession, especially, I should anticipate that the work would be received among them, even without the injunction of the authorities, who would, however, I think, find it to the interest of the service to sanction it.

Allow me to say, that I consider the work fully to sustain the high character for scientific acquirement, which I have always heard attributed to its author.

Respectfully yours,
A. D. BACHE, Prof., &c.

The undersigned are of opinion that the work of Lieutenant M. F. Maury, on Navigation, is eminently useful as a school book for nautical students. It illustrates with clearness and simplicity, the principles on which the calculations in navigation are founded.

We felt the want of just such a book in aid of our early studies, and cheerfully recommend it to all who desire to inform themselves in this branch of education, with a view to the nautical profession.

FRANCIS H. GREGORY, Capt.
ROBERT F. STOCKTON, Capt.
FREDERICK ENGLE, Com.
G. A. MAGRUDER, Com.

MY DEAR SIR:

I have great pleasure in stating my belief that it is of the utmost importance that the midshipmen of the navy should have some established work, containing within itself all the information on mathematics and navigation, including nautical astronomy, which they are required to know in order to pass an examination for promotion. Such a work should be strictly elementary, and embrace arithmetic, algebra, geometry, and plane and spherical trigonometry, so far, and so far only, as might be necessary to the construction of all the rules and formulæ requisite to solve the various problems in navigation and surveying. When I was preparing for examination, I felt an earnest desire to possess this information, and to ascend step by step to a complete understanding of the whole subject, so as to have the means of reaching all the processes of which I availed myself by my own resources, without taking any thing on trust. After my promotion I devoted my whole time and attention, for a considerable period, in attaining this object; and feeling how much my own course had been impeded by the want of books containing the required knowledge, I carefully preserved all that I had recourse to for the purpose; such as La Croix, Bezout, Legendre, Lassalle, Borda, and Callet, and determined at my earliest leisure to compile from them a treatise, narrowed down to what was indispensable, so as to spare others, ambitious of more complete information on this branch of professional knowledge than is usual, the great difficulty I had experienced in knowing where to apply for information. The appearance of your work, so exactly supplying what was needed, and, from your infinitely higher mathematical attainments, executed in so superior a manner, to what it would have been had the task been left to me, took from me all motive and desire to go on with the undertaking. After having exerted such commendable exertion, ingenuity, and judgment in accomplishing your task, I trust you may, at least, have the satisfaction of seeing your work generally used by the midshipmen, if not as a manual of practical navigation, which Bowditch's admirable work so effectually supplies, at least as an elementary treatise for the instruction of the young officers of the navy, the more acceptable and encouraging for having been supplied by one, who was, at the time, of their number.

Believe me, very truly,
And respectfully yours,
ALEX. SLIDELL MACKENZIE,
Commander, U. S. Navy.

TARRYTOWN, 14th November, 1843.

I should not hesitate to commend Maury's Navigation for the use of the midshipmen of our navy. To those of them who are advanced in the elements of the science, it supplies the *practical* information necessary to make them good navigators; and to others, who have commenced with the *practice*, (which often happens) the explanations

of the principles are both ample, easy, and well arranged.

The work, I know, originated in the *wants* of the students of navigation on board ships, and I confidently believe that it will supply those wants.

L. M. POWELL,
Commander, U. S. Navy.

U. S. NAVY YARD, GOSPORT,
8th January, 1839.

SIR:

I am much pleased with your "Treatise on Navigation." The mathematical investigations it affords of the principles of the science, particularly of nautical astronomy, place it upon different grounds from the treatises upon the subject in common use, and adapt it much better to the purpose of instruction. I am desirous of introducing it, as far as may be practicable, among my own classes; and recommend it to all the younger officers in our naval service, who desire to become acquainted with the theory, as well as the practice of the mathematical part of their profession. Its designation as one of the books to be used in their examination, would, I think, conduce to elevate the standard of mathematical attainments among them.

With great regard,
Your obedient servant.
JOHN H. C. COFFIN.
Prof. of Mathematics, U. S. Navy.

WASHINGTON, 20th Dec., 1842.

DEAR SIR:

I have been much interested in a hasty examination of your work upon *Navigation*, more particularly with that part of it, which relates to "Spherical Trigonometry," and "Nautical Astronomy," two branches of navigation that have been too superficially treated in the most popular works upon the subject, to answer the increasing general information of the practical navigators of the present day.

During the last forty years, but little improvement of this kind has been introduced into the standard works upon navigation, and as a general remark, it may be safely asserted that they are behind the wants of those who use them.

Ever anxious for the general diffusion of such important knowledge in our profession, I trust you will be encouraged to introduce the work into the navy as a *Text-Book*. I remain, respectfully, etc.,

JAMES GLYNN,
Commander, U. S. Navy.
Lt. M. F. MAURY, U. S. N.

U. S. SHIP DALE, 23d Oct., 1843.

I feel great pleasure in recommending Maury's Navigation as a work of real usefulness and importance to the young officers of our navy.

It imbodies whatever can be of utility to the navigator, in a concise and perspicuous manner; and its explanations and references are calculated to excite, in youthful and industrious minds, a desire for the higher mathematical attainments. Having used the work myself, I know its value, and, therefore, hope it will become the authorized book of study for the midshipmen of our navy.

THOS. A. DORNIN,
Commander, U. S. Navy.

FLAG SHIP PENNSYLVANIA,
November 4th, 1843.

MY DEAR SIR:

I have, with great pleasure and care, examined your book on Navigation, and do decidedly recommend and prefer it to any other in use. The mathematical principles condensed in such a form, is a sufficient recommendation to every student of navigation, and I recommend it to all mathematicians and young officers belonging to, and at schools attached to the navy, and should think that the Hon. Secretary of the Navy would so order it.

I have the pleasure to remain, with regard,
Your obedient servant,
E. P. KENNEDY,
Lt. M. F. MAURY, U. S. N. P. C., Norfolk.

U. S. SHIP PENNSYLVANIA,
Nov. 3d, 1843.

SIR:

I have been much gratified in the perusal of your Treatise on Navigation; and think it well adapted for use as a school book, and one best calculated, of any that I have seen, to induce a love for the prosecution of the study of navigation as a science, and not merely as an art.

I am, very respectfully,
Your obedient servant,
A. G. PENDLETON,
Prof. of Mathematics, U. S. Navy.
Lt. M. F. MAURY, U. S. N.

U. S. SHIP OHIO, BOSTON,
Nov. 14th, 1843.

SIR:

I have examined, with a good deal of attention, your Treatise on Navigation, and find it embraces all the elements necessary to constitute a scientific navigator. It would, I believe, be found a valuable auxiliary in our naval schools.

The work of Dr. Bowditch, although eminently useful as a *practical* one, fails almost entirely in the development of the principles from which its rules are derived.

It seems, therefore, desirable, that some work explaining more fully the *theory* of navigation should be put into the hands of our midshipmen, in order that they may become, as we all desire, *scientific* as well as practical navigators.

Hoping that the pleasure of furnishing such a work for the younger officers of the service may be yours,

I remain, very respectfully,
Your obedient servant,
JOS. T. HUSTON,
Prof. of Mathematics, U. S. Navy.
Lt. M. F. MAURY, U. S. N.

U. S. SHIP BOSTON, BOSTON,
Nov. 15th, 1843.

DEAR SIR:

I am much pleased to learn, through the

Digitized by Google

Army and Navy Chronicle, that a new edition of your valuable Navigator is soon to be published.

I cannot doubt the success of a large second edition, and I am confident that it will add to your reputation, and secure for your book the celebrity which it deserves. Its merit is recognised in the navy, and I would recommend it in all schools of navigation, particularly on account of the manner in which many difficult and obscure points are made easy and plain.

Respectfully, etc.,
G. J. PENDERGRAST.
Commander U. S. Navy.
Lt. M. F. MAURY, U. S. Navy.

WILMINGTON, Del. Nov. 5th, 1843.

I consider Maury's Treatise on Navigation, the very work that has long been wanting in our schools, and I hope it will eventually be used in all of them (particularly the naval ones) instead of Bowditch's Practical Navigator; for I think it far superior as a book of instruction.

J. SHUBRICK,
Commander, U. S. N.

NORFOLK, Nov. 7th, 1843.

I think Maury's Navigation is admirably adapted for the instruction of the young officers of the Navy. All the problems are deduced from theorems, in such a manner as to give the young seaman a correct idea of the theory as well as the practice of navigation. The methods are simple and accurate, and the tables well and carefully constructed. The work contains all that the student of navigation can require; and, were it made the authorized text book of the Navy, the standard of mathematical attainments among midshipmen, would be greatly elevated.

R. B. CUNNINGHAM.
Commander, U. S. Navy.

NOVEMBER 8th, 1843.

I possess a copy of Maury's Navigation, and consider it a valuable text-book for all nautical students, whether in the United States Naval Service, or in the commercial marine.

The author, Lieutenant M. F. Maury, U. S. Navy, is a man of science, and has produced this work under the advantage of knowing from experience what the nautical student and practical navigator require.

S. P. LEE,
Lt. U. S. Navy.

U. S. NAVAL HOSPITAL,
New York, Nov. 10th, 1843.

SIR:

Your volume seems to me well calculated to achieve the object for which it seems designed: namely, to demonstrate the formulas of Nautical Astronomy, and explain the principles upon which the art of navigation is founded. A better book for schools of navigation, than yours, I am persuaded does not exist in our language. But after the expression of favourable opinions of it, by such men as Bowditch, Alexander Dallas Bache, P. J. Rodriguez, Edward C. Ward, and John H. C. Coffin, all eminently qualified to judge of such a work, few can doubt its worth or set any value upon the opinion of,

Very respectfully,
Your obedient servant,
W. S. W. RUSCHENBERGER,
Surgeon, U. S. N.
Lieut. M. F. MAURY, U. S. Navy.

U. S. SHIP CUMBERLAND,
Boston, Nov. 14th, 1843.

DEAR SIR:

From the cursory examination I have given your treatise on navigation, I, for one, am proud that so useful and valuable a work has been furnished by one of our own corps.

With the improvements you propose to add in the new edition you are preparing, I doubt not it will possess advantages over other works of the kind, and be found a valuable auxiliary in our naval schools.

Very truly yours,
JOSEPH SMITH,
Captain U. S. Navy.
Lieut. M. F. MAURY, U. S. Navy.

WASHINGTON CITY, Nov. 23d, 1843.

DEAR MAURY,

I take this occasion to express to you the pleasure I feel, in noticing the announcement of a new edition of your treatise on navigation. Its subject matter being strictly professional, has called for the close scan of many of your brother officers, myself of the number. Its worthiness to become the text book of our young naval officers, may, with propriety, be judged of by those who are called on to exhibit a certificate of having been closely examined on, and found to possess a thorough knowledge of the subject treated of in your book alluded to.

Without an exception, all of our brother officers, and they are many whom I have heard descant freely on the merits of your work on navigation, pronounced it to be the best text book on that subject extant. In a full concurrence with that opinion,

I am with much esteem,
Respectfully yours truly,
WM. W. HUNTER,
Lieut. U. S. Navy.
Lieut. M. F. MAURY, U. S. Navy.

U. S. BRIG PERRY,
Norfolk, Va., Nov. 24th, 1843.

DEAR SIR:

I am pleased to learn you are preparing an improved edition of your Navigation, more especially with the view of instructing the midshipmen in the theory of navigation. To carry the student beyond the mechanical solution of nautical problems, into a comprehension of those principles of Mathematics and Astronomy, upon which these problems are based, seems to have been wanting in most treatises on Navigation.

Digitized by Google

Even Dr. Bowditch's invaluable epitome, that has laid every American, who has to trace his way on the great deep, under a lasting debt of gratitude, is wholly practical in its method. But the value of a Class Book proposing to teach the young officer the theory of one branch of his profession, which imbues his mind with some tincture of science, and raises him above the blind worker of mechanical problems, need not be enlarged upon; though it cannot be better appreciated than by those in the profession, who were deprived of the many advantages now offered to our midshipmen, and who were compelled to prepare for their examination with a Practical Navigator for their sole instructor, and a campstool between two guns, for their study room.

Uniformity in instruction too is a matter of great importance, and not doubting that the superior authority, who alone can prescribe the book to be taught, will fully appreciate the honorable contribution afforded by your work, to the character and benefit of the Navy, and that it will be made the standard at the examination of midshipmen, I remain, my dear sir,

Very sincerely, &c.
S. F. DUPONT,
Commander, U. S. N.

Lieut, M, F. MAURY, U. S. Navy.

ST. AUGUSTINE, E. FLORIDA, Nov. 27th, 1843.

My opinion can contribute nothing to the established reputation of your valuable work. I can only say, that when I first looked through it, I considered it as thoroughly supplying the great desideratum of a midshipman's study of navigation, and remarked to those who were present, "How unfortunate were we, in not having such a book when we were students of navigation." My opinion has been confirmed by that of other and more competent judges, and I believe that throughout the entire service, there has not been a disparaging voice raised against it. I regard it as being to Bowditch what Bowditch was to Hamilton Moore.

Respectfully, &c.
WM. F. LYNCH,
Lieut. U. S. Navy.

Lieut. M. F. MAURY.

YALE COLLEGE, CONN. October 26th, 1843.

This valuable work on Navigation, theoretical and practical, it seems to me desirable to have placed in the hands of every naval officer, who may have occasion to navigate a ship or to explain the principles of Nautical Astronomy. These are well brought out, and illustrated with examples of their application, which render the treatise clear and intelligible, and adapt it well to the purposes of a text book for learners. With this book as a guide in the *rationale* and principles of navigation, and Bowditch as a companion in the practical computations, the young officers of our Navy may be well prepared for the important and responsible duties of navigators. Having formerly used the work at sea, while engaged as an instructor in the naval service of the U. S., I cordially give it this recommendation.

JAMES NOONEY, Jr.
Tutor in Nat. Philosophy,
Late Prof. of Math. U. S. N.

SURVEYING SCHR. GALLATIN, Philadelphia, Dec. 13th, 1843.

DEAR SIR:

I have learnt with pleasure that a second edition of your work on Navigation will shortly be published.

I have always considered this book, from its general arrangement, and the kinds of solution employed, as decidedly the best work for students extant.

Believe me, truly yours,
(Signed) GEO. S. BLAKE.

Lt. M. F. MAURY, U. S. N. Washington.

Opinion of Capt. M'INTOSH, U. S. N. NEW YORK, Dec. 12th, 1843.

It affords me great pleasure to state, that I consider your work on Navigation, as one of the very best now extant, and most cheerfully recommend it as most suitable for a school book for midshipmen.

Lieut. MAURY.

Opinion of Capt. PERCIVAL, U. S. N. U. S. SHIP CONSTITUTION, Gosport, Dec. 14th, 1843.

In compliance with your request, I have perused Maury's "New Theoretical, and Practical Treatise on Navigation," and have found it, as far as I am able to judge, a convenient reference, in illustrating the principles of Nautical Astronomy. Its explanations of the principles of Spherical Trigonometry, and its application of them to the solutions of the various astronomical problems, so essential in navigation, render it a book, in my opinion, not only useful as a supplement to our first (Bowditch's) standard work on the subject; but valuable in itself: an acquisition to the nautical student, who, if he is desirous of acquiring a correct, and practical knowledge of his profession, may be largely aided by the study thereof.

Lt. M. F. MAURY, U. S. N.

Opinion of Capt. FORREST, U. S. N. WASHINGTON, Dec. 18th, 1843.

I take much pleasure in recommending your "New Theoretical and Practical Treatise on Navigation." The explanations and illustrations are rendered clear and comprehensive, and I believe it to be just such a production as we require for the instruction of the young officers of our Navy, as well as others desirous of obtaining a well grounded and accurate knowledge of the science.

Lt. M. F. MAURY, U. S. N.

Digitized by Google

Opinion of the U. S. Naval Lyceum, Brooklyn, New York.
BROOKLYN, Dec. 20th, 1843.

The undersigned, a committee to which was referred Lieut. Maury's "Treatise on Navigation," report that they have carefully examined the same, and are of opinion that it is a work well adapted for the instruction of the young officers of the Navy, as all the problems and formulæ that are necessary in their profession, are there brought together in a condensed form, and so clearly, and concisely demonstrated, that the student may easily inform himself of the theory and principles on which his practice is founded; and the accompanying tables are so constructed as to facilitate his calculations; all of which are systematically arranged, with a simplicity that has heretofore been generally wanting in works on Navigation. They would therefore recommend the same to be adopted for the use of the Naval schools.

Signed,
J. H. STRINGHAM,
WM. D. NEWMAN,
ALEX. C. GIBSON.

The following opinions have already appeared in print, but as they have in all probability escaped the notice of many to whom these pages will be presented, they are again inserted here.

"*U. S. N. S., New York, January* 19, 1836.

"Dear Sir,—I have had much pleasure in the perusal of your "New Theoretical and Practical Treatise on Navigation;" the plan and arrangements of which are original; it contains little or nothing superfluous, and every part of it appears to be as clear and intelligible as the nature of the subject will admit. Such a work has long been wanted in our Naval Schools, and on board our vessels of war. I intend to make use of it in the Naval School on this station; and I recommend it to be used by all the professors of Mathematics and Nautical Science, in the Navy of the United States.

"Yours Respectfully,
"EDW. C. WARD,
"Prof. Math. U. S. Navy."

"Passed Midshipman M. F. Maury,
"U. S. Navy."

"*U. S. Navy Yard, Gosport, March* 7, 1836.

"I have examined a Treatise on Navigation written by M. F. Maury of the U. S. Navy; and have no hesitation in recommending it to the students of that science. The explanations are clear, the rules are illustrated by many examples, and the new arrangement of some of the tables simplify the calculations of the navigator. Mr. Maury is deserving of great credit for the work, and I wish him every success.

P. J. RODRIGUEZ.

MAURY'S NAVIGATION.

AN ELEMENTARY, PRACTICAL, AND THEORETICAL TREATISE ON NAVIGATION: WITH A NEW AND EASY PLAN FOR FINDING DIFF. LAT., DEP., COURSE, AND DISTANCE BY PROJECTION. BY M. F. MAURY, LIEUT., U. S. NAVY.

ADDITIONAL OPINIONS OF NAVIGATORS.

Opinion of Capt. GEISINGER, U. S. N.
BALTIMORE, Dec. 13th, 1843

I have not seen your work on Navigation, since a short period after its publication. At that time, I thought very favourably of it; and from my recollections, should suppose it well adapted as a school book for midshipmen.

Lieut. MAURY.

Opinion of Capt. J. C. LONG, U. S. N.
EXETER, N. H., Dec. 16th, 1843.

I regret it is not in my power to express an opinion, from actual examination, of your work on Navigation. But I take pleasure in saying I have often heard it spoken of as the best work extant, for the use of Midshipmen.

Lt. M. F. MAURY.

Opinion of Capt. SKINNER, U. S. N.
NORFOLK, Dec. 17th, 1843.

My pursuits of late years have been so diverse from those of mathematical science, that I do not feel qualified to decide absolutely on the merits of your "work on Navigation;" but so far as I am enabled to form an opinion (from recent examination,) it appears to me to embody in a clear and concise method, every thing necessary to form a theoretical as well as a practical Navigator, and therefore, well adapted for a text book for the midshipmen of our Navy.

In this opinion I think I am sustained by others better able than myself to form a correct judgment on the subject, and to whose opinions I would readily yield my own.

Lt. M. F. MAURY, U. S. N.

Opinion of Capt. SAUNDERS, U. S. N.
WASHINGTON, Dec. 20th, 1843.

I have examined with some care, your treatise on Navigation, and take great pleasure in recommending it as a work well calculated as a text book for the Navy.

I am happy to add, that I have been confirmed in the above opinion by all the officers of the Navy with whom I have conversed.

Lieut. M. F. MAURY, U. S. N.

Opinion of Lieut. H. H. BELL, U. S. N.
U. S. STEAMER "UNION," Dec. 20th, 1843.

I have looked over your Treatise on Navigation with great interest and profit, and have no where met with a single volume which treats so satisfactorily of the Elementary Mathematics, and of Theoretic Navigation at the same time; or, which introduces one so thoroughly to the mathematical principles of Navigation and to the practice too.

I hope the work may come generally into the hands of seamen, and that you may be compensated for your useful labours.

Lt. M. F. MAURY, U. S. N.

Opinion of Capt. GUINN, U. S. N.
PHIL. Jan. 16th, 1844.

I take great pleasure in stating that I consider your work on Navigation exceedingly well adapted to the use of students, from the fact that spherical solutions are given in all the problems in Nautical Astronomy, in the most clear and lucid style; and the general arrangement of the work is exceedingly good. I have heard it also spoken of very favourably by many officers.

Lieut. M. F. MAURY, U. S. Navy.

Opinion of Lt. C. RINGGOLD, U. S. N.
BALTIMORE, Jan. 18th, 1844.

I have lately observed that your "Elementary Treatise on Navigation" has reached its second edition. The former I had in my possession since its first appearance.

I take pleasure in bearing my humble testimony to its merit and utility as a work of instruction for the naval student, and of advantage to the practical navigator. It appears to me to be a compendium and arrangement of those portions of mathematics and astronomy, most proper and conducive to the purposes of the student, and equally comprehensive.

I feel proud that a brother officer should have successfully devoted himself to the production of a desideratum, alike advantageous to the Navy, and highly creditable to himself.

Lt. M. F. MAURY, U. S. N.

Opinion of Lt. BOUTWELL, U. S. N.
WASHINGTON, Jan. 27th, 1844.

I have examined with care, your book intended for the instruction of the young officers of the Navy.

In my opinion, such a work will be a valuable one to them, and to nautical men generally; and is not only creditable to yourself, but to the service, of which you are a useful member.

Lt. M. F. MAURY, U. S. Navy.

Opinion of Lt. CARR, U. S. N.
WASHINGTON, Jan. 29th, 1844.

I have always considered your "Treatise" as a most valuable text book for midshipmen —in fact the *very* book so long needed for their proper instruction.

I can only add, that for my own purposes, I have preferred it to Bowditch, Riddle, or Inman.

Lieut. M. F. MAURY, U. S. Navy.

Google

Opinion of J. S. J. SHIPLEY, Act'g Master, U. S. S. FALMOUTH, Jan., 1844.

I have examined, with some care, a Treatise on Navigation, by M. F. Maury, U. S. N., and have no hesitation in recommending it as one of the best works now in use.

Opinion of Lt. CHANDLER, U. S. N. U. S. S, Falmouth, Jan. 31st, 1844.

Accept, as my unqualified opinion, all that has been said in favour and in recommendation of your highly useful and valuable work.

Lieut. M. F. MAURY, U. S. Navy.

Opinion of Commodore WM. B. SHUBRICK. WASHINGTON, Feb. 3d, 1844.

I take pleasure in bearing testimony to the value of your "Elementary, Practical, and Theoretical Treatise on Navigation." It is certainly the best professional work in my judgment, that can be placed in the hands of the young sea officer.

Lt. M. F. MAURY, U. S. N.

Opinion of Lt. UPSHUR, Commander, U. S. BRIG TRUXTUN, Feb. 5th, 1844.

During my late cruise in this brig, I often used your "Treatise on Theoretical and Practical Navigation" in determining my position at sea, and for other purposes connected with my duties as the Commander of a vessel of war. I had also frequent occasion to refer to it, for first principles in Astronomical and Trigonometrical calculations.—I take great pleasure in stating that I never appealed to it in vain, for any information which it professes to give; neither had I in any instance the slightest difficulty in comprehending at a glance, any one of the concise and lucid definitions and explanations it contains.

Where all is good, it is difficult to award the preference to any particular branch, but I was forcibly impressed with the great value of that part of the work devoted to Nautical Astronomy. The system of Double Altitudes, for determining the Latitude, (confessedly a most important branch of Navigation, and unfortunately hitherto too little resorted to, because, for want of accurate rules, neither well understood, nor generally confided in,) I consider decidedly the best I have ever seen, not excepting Doctor Keith's highly approved rules. For purposes purely practical, I think your work fully equal to any emergency which can present itself to the Navigator at sea. As a Theoretical and Elementary Treatise for the use of students in Navigation, it is certainly superior to any other extant, and while I am justly proud that the honour of its paternity belongs to a member of my own corps, I sincerely hope that his labours for the general good may be rewarded by its immediate adoption, as a text book, into the Naval and other Nautical schools throughout the Union.

Lt. M. F. MAURY, U. S. N.

We, the undersigned, are of opinion that "Maury's Treatise on Navigation," has superior merits as a book of instruction, to any compilation on this science, extant.

It supplies a great desideratum, by combining and demonstrating, in so lucid but condensed a form, the Theory with the practice. That a scientific and professional work of such established reputation, should have been produced by one of our own corps, adds greatly to our satisfaction in recommending it as a text book to all students of Navigation—as such, we trust it will be authorized and used in the Navy.

(Signed) GEORGE BACHE, J. C. WALSH, CHARLES STEEDMAN, J. HUMPHREYS, Lts. U. S. N.

Washington, Feb. 5th, 1844.

Opinion of Capt. WYMAN, U. S. Navy. BOSTON, Feb. 9th, 1844.

Your work, entitled a "Theoretical and Practical Treatise on Navigation," is, in my estimation, eminently calculated for the use of those who wish to acquire a thorough knowledge of Navigation, to learn the principles upon which the whole subject is founded, and to carry those principles into practical operation.

Consequently, I believe it to be the best Treatise of the kind extant, for the use of the young officers of our Navy, as well as for those of our Mercantile Marine, from which to acquire the Theoretical and Practical knowledge pertaining to the science of Navigation.

The explanations in Algebra, as well as those in Logarithms, Trigonometry, Spherics, and other subjects under the head of Nautical Astronomy, are lucidly given by diagrams and otherwise, and the subjects admirably arranged for the advancement of the student. Those likewise in Surveying, are concisely expressed; but seem to include all that is requisite to a competent knowledge of the practical operations for conducting of a survey to a successful termination.

Lt. M. F. MAURY, U. S. N.

Opinion of GEO. M. TOTTEN, Lt. U. S. N. WASHINGTON CITY, Feb. 9th, 1844.

I have used your Navigation since it was first published. I preferred it to any other, when studying for my own examination; and with it, have prepared more than a dozen midshipmen for their examination—all of whom have passed creditably.

I consider it invaluable as a text book, particularly to midshipmen; for it enables them to understand the construction of rules and formulæ, which they are but too apt to learn only by rote; and which, therefore, are forgotten almost as soon as learned.

Lt. M. F. MAURY, U. S. N.

Opinion of Lt. MISSROON, U. S. N. BOSTON, Feb. 20th, 1844.

That so excellent a work as yours, should have emanated from one of our corps, (certainly the most appropriate source,) has, since its appearance, been a matter of professional exultation to your brother

officers, and in which I have largely participated.

I should not have withheld till this period, an expression of my favourable opinion of its suitableness for a school book in Naval seminaries, as well as for the sea companion of the more advanced Nautical man, had I deemed my poor opinion of sufficient weight to work a favourable influence for it. Indeed, I had not imagined that there could have been a question or hesitation on the subject.

In the several instances where my advice has been sought by those interested in the advancement of certain young midshipmen, your book has been recommended in preference to any other heretofore in use.

I trust, for its own merits and for your sake, that it may be adopted as the standard work on Navigation in our Naval schools.

Lt. M. F. MAURY, U. S. N.

Opinion of J. H. GRAHAM, Com'r. U. S. N. } NEW YORK, Feb. 22d, 1844. }

I can hardly conceive that any expression of mine is wanting to add force to the profound demonstrations in favour of your work.

It is one of those productions possessing so many points of attraction, that it may with propriety be said to pronounce its own excellence.

I sincerely hope, therefore, for your sake, and for the benefit of those who aim at the acquisition of scientific knowledge, that it may be generally adopted in the institutions of learning, as a work admirably calculated to conduct the mind from the incipient to the more profound stages of Nautical science.

Lt. M. F. MAURY, U. S. N.

Opinion of Lt NORTH, U. S. N. } U. S. S., Plymouth, Feb. 22d, 1844. }

It gives me great pleasure to recommend Maury's Navigation. It is, in my opinion, a most valuable and useful work; one that every midshipman should have. Such a work we have long wanted. I hope it will be introduced and used in all our Naval schools, as well as in the Merchant Marine.

Lieut. M. F. MAURY, U. S. N.

Opinion of C. O. HANDY, U. S. N. } WASHINGTON, Feb. 23d, 1844. }

It gives me pleasure to express my deep interest in the success of your work on Navigation, as a manual for the officers of the Navy, by its being adopted as a text book, by the Department.

I have carefully examined it, and discover in it a desideratum, hitherto much wanted, especially in Bowditch—I mean a clear elementary exposition of the principles of Nautical Astronomy and practical Navigation—sufficiently developed for practical purposes. The superior qualifications, which, since the regulation for the examination of midshipmen, have been required for promotion, will, I think, render your work an indispensable auxiliary to the Service.

Lt. M. F. MAURY, U. S. N.

Opinion of Capt. SLOAT, U. S. N. } NEW YORK, Feb. 24th, 1844. }

I have great pleasure in stating that, in my opinion, your work on Navigation and Nautical Astronomy is of the greatest importance to the Officers of the Navy, and all persons engaged in the Mercantile Marine, supplying, as it does, the principles on which the calculations are founded, with a simplicity and clearness not to be found in any other work with which I am acquainted.

The great want of such a work has been sadly experienced by all persons commencing the study of Nautical Astronomy and practical Navigation,—particularly our young officers—since the establishment of the Board of Examination, to whom I cordially and confidently recommend it, as well as to all others desirous of acquiring a theoretical and practical knowledge of that branch of the profession of a seaman.

Lt. M. F. MAURY, U. S. N.

Opinion of V. M. RANDOLPH, Com'r. U. S. N. } COLUMBUS, Miss. Feb. 25th, 1844. }

I am glad to hear that you are about to publish a second edition of your valuable work on Navigation. Permit me to say, that in my humble opinion it is the very best elementary treatise of the kind that has fallen under my notice.

I had been in the Navy many years, before I knew any thing of the first principles of Navigation, and in common with hundreds of other "Reefers," merely made myself acquainted with the *rules* in "Bowditch," as the parrot school-boy does with his painfully conned lesson. But about twelve months before my examination came on, I had the good fortune to meet with "Kelly's Spherics;" and there, I found that Nautical Astronomy is, in truth, a beautiful science, and that no one, ambitious of distinction in our profession, ought to remain satisfied with only mastering the rules of Dr. Bowditch.

In short, your treatise is the very one which we have long needed, and I sincerely hope it will be adopted as the text-book in our Navy.

Lt. MAURY, U. S. N.

Opinion of Capt. STORER, U. S. N. } U.S. N. Yard, Portsm'th, N.H., Feb. 26, '44. }

My opinion cannot contribute to the reputation, already established, of your valuable work. I will state, however, that it appears to be, in an eminent degree, admirably adapted for a school book, in the mercantile, as well as the military marine.

Lieut. M. F. MAURY, U. S. N.

Opinion of CHAS. H. BELL, Com'r. U. S. N. } BELVIDERE, Feb. 26th, 1844. }

I have learned with much pleasure, that you are about to publish a new edition of your work on Navigation.

To Midshipmen preparing for an examination, as well as others anxious to attain a knowledge of this branch of our profession, it is a work long needed as an auxiliary to Bowditch, particularly to those who have not the advantage of a teacher at hand, to

Digitized by Google

explain the *rationale* of many parts of that valuable book.

On a cursory view of your work, when first published, I soon observed how much labor it would have spared me, while preparing for my examination, if such a book could then have been obtained. I would therefore, without hesitation, recommend it to be used in all schools where the theory of Navigation is taught.

M. F. MAURY, Lt. U. S. N.

Opinion of JAS. T. GERRY, Com'r. U.S. N. }
NEW HAVEN, Feb. 26th, 1844. }

I consider your "Treatise on Navigation" a compilation of the most desirable elements for progressive advancement in the study of Nautical science, and think it must prove an able pilot and valuable assistant to the young student.

M. F. MAURY, Lt. U. S. N.

Opinion of Lt. SELFRIDGE, U. S. N. }
Navy Yard, Portsmouth, Feb. 26th, 1844. }

I take pleasure in saying that I consider your "Treatise on Navigation" a valuable work to nautical men, and a useful text-book to students in the Navy.

Lt. MAURY, U. S. N.

Opinion of Lt. WALKER, U. S. N. }
Philadelphia, Feb. 26th, 1844. }

I consider that "Maury's Navigation" has supplied the wants, so severely felt, prior to its appearance, by students of Navigation.

Opinion of Lt. GEO. T. SINCLAIR, U. S. N. }
NORFOLK, Feb. 26th, 1844. }

I do not think that any young officer should be without your "Treatise on Navigation." I should be very much pleased to see it adopted by the Navy Department as a text-book for midshipmen.

Under the present system, few of them *understand* the principles on which the simplest rules of Navigation are founded, and this could not be the case if they were required to pass an examination on your work.

Lt. M. F. MAURY, U. S. N.

Opinion of Lt. S. B. BLUNT, U. S. N. }
PHILADELPHIA, Feb. 26th, 1844. }

In "Maury's Navigation" we have a work peculiarly adapted to the wants of students of navigation. Its advantages are many. The method of reasoning which the author has adopted, is purely mathematical; leaving nothing to be taken for granted;—leading one up from the simplest truths to the most difficult demonstrations, as it were, by a gradually inclined plane, never fatiguing the mind, but leaving it satisfied with every step it has taken.

It presents to the student, a clear, complete, but concise treatise on Spherical Geometry and Trigonometry, which will enable him, with a few hours' diligent application, to acquire a clear and settled comprehension of all the principles on which the rules for solving problems in Nautical Astronomy are founded.

This Treatise is not so condensed as to require a laborious effort of mind to understand it; nor is it so prolix that the student has to wade through a thousand unnecessary difficulties, before he reaches his desired end. The principles of spherics are here so plainly and so directly applied to the illustration of Navigation, that the student finds the long and apparently confused rules by which he has been thus far guided—if he have studied Bowditch only—at once cleared of the obscurity in which they were enveloped: he sees them stand forth, a beautiful concentration of all the useful parts of the problems entering into the solution of the questions proposed. The tables are complete and comprehensible. As a highly useful work for the instruction of young Naval officers, I do not think it can be too strongly recommended as *the* text book in all our Naval schools; and I should feel the more pleasure in seeing it introduced as such by authority, as it is the production of a Naval officer.

Lt. M. F. MAURY, U. S. N., Sup't. Depot of Charts, &c., Washington, D. C.

Opinion of Capt. SALTER, U. S. N. }
NEW YORK, Feb. 27th, 1844. }

I take pride in recommending your book upon Navigation to all Navy students, and trust that the Hon. Secretary of the Navy may think proper to order it used in Navy schools; it reflects much credit upon your researches in Mathematics, and adds to your already high standing in the service.

Lt. M. F. MAURY, U. S. N.

Opinion of Lt. WM. M'BLAIR, U. S. N. }
PHILADELPHIA, Feb. 28th, 1844. }

I am familiar with your Treatise on Navigation, and have frequently recommended it as the best work of the kind, to place in the hands of the young officer.

I hope sincerely to see it generally adopted, believing that it affords the most effectual and agreeable method of acquiring a knowledge of Navigation.

Lieut. M. F. MAURY, U. S. N.

Opinion of Commodore READ, }
U. S. Navy Yard, Phil. Feb. 29th, 1844. }

I conceive your "Treatise on Navigation" to be well adapted to the use you design to make of it—that of a school-book for midshipmen, and students of Navigation generally. If I could entertain a doubt of its usefulness for the purpose proposed, the good opinion expressed of the work by Professor Bache, would lead me to believe I was in error.

Lt. M. F. MAURY, U. S. N.

Opinion of Capt. LAVALLETTE, U. S. N.

Captain Lavallette has heard Maury's Navigation spoken of in terms of high commendation, but not having met with the Treatise, is consequently, unable to give his opinion from personal inspection.

U. S. Navy Yard, Pensacola,
March 2d, 1844.

Opinion of Commander YOUNG, U. S. N.
PORTSMOUTH, Va., March 2d, 1844.

I regard your work on Navigation as eminently entitled to the notice of all persons interested in sound Nautical education; and believe that its adoption as *the Text Book* in our Naval schools, would result favourably to the high interests and requirements of the service.

Lt. M. F. MAURY, U. S. N.

Opinion of E. PECK, Commander, U. S. N.

I have carefully and diligently perused a work on Navigation, by Lt. M. F. Maury, U. S. N., and hesitate not in saying that in the arrangement of its Tables, its condensed form and perspicuity, I consider it vastly superior to any book of the kind I have ever made use of.

NEW YORK, March, 1844.

Opinion of S. B. WILSON, Com'r, U. S. N.
CLERMONT, March 7th, 1844.

I am glad of an opportunity to offer my mite of commendation in favour of your Treatise on Navigation. Such a book has long been wanted. It illustrates the theory and practice of scientific navigation so concisely, as to leave no doubt of its ultimate adoption, not only as a class book for the instruction of young officers at the naval schools, and of others destined for the sea as a profession; but for all practical use on board ships both of the navy and of our commercial marine. The necessity of a uniform system of instruction and practice, both at school and on board ship, cannot be questioned: and these, I think, will be eminently attained by the introduction and use of your book. I am much pleased to hear you are about to publish another edition of this valuable work.

Lt. MAURY, U. S. N.

Opinion of J. T. M'LAUGHLIN, Lt. U. S. N.
WASHINGTON CITY, March 8th, 1844.

I take great pleasure in recommending your work on Navigation to the younger officers of the Navy.

I have used it, know its value, and look upon it as the best elementary Treatise that can be put into the hands of the youthful Navigator.

M. F. MAURY, Lt. U. S. N.

Opinion of R. SEMMES, Lt., Commanding U. S. Surveying Steamer POINSETT.
TAMPA BAY, March 10th, 1844.

I greeted the appearance of the first edition of your Treatise on Navigation and Nautical Astronomy, with great pleasure, as supplying a want which had long been felt by myself, in common with other young officers of the Navy, and I am pleased to hear that another edition of it has recently passed through the press. I add my testimony cheerfully to that of others who have spoken, and who are so much more competent than myself, to pass an opinion—as to its merits as a text book for the naval schools, as well as a manual in the hands of the practical Navigator.

It seems to me, to contain every thing necessary, as well for the understanding of Navigation as a science, as for the practice of it as an art; and nothing superfluous. The standard of mathematical acquirements with us, ought certainly to be raised, and no officer should be permitted to pass an examination for promotion, who cannot *demonstrate* as well as *rehearse* the rules of Navigation.

I have no doubt whatever, that your work will finally supersede every other book of the kind, in the Naval service at least. I feel proud that so valuable a contribution to Nautical science, has been made by a member of our own corps.

Lt. M. F. MAURY, U. S. N., Bureau of Ordnance and Hydrography, WASHINGTON CITY.

Opinion of Commodore WILKINSON, U. S. Navy Y'd, GOSPORT, March 11, 1844.

I regret that I have not sufficient leisure to give your work on Navigation a thorough examination; but I have seen enough to convince me that it will be found a most useful work, particularly in our Naval schools, and that it redounds much to the credit of its author.

Lt. M. F. MAURY, U. S. N.

Opinion of Capt. CRABB, U. S. N.
PRINCETON, March 12th, 1844.

Your work on Navigation has not fallen under my observation, attributable to my inactive position in the Navy, for the past six or seven years.

The warm commendations of it by Navigators and Professors—many of whom I am personally acquainted with—and your own character for scientific acquirements, tend, nevertheless, to place the book high in my estimation.

Lt. M. F. MAURY, U. S. N.

Opinion of Lt. S. JOHNSTON, U. S. N.
LOUISVILLE, Ky., March 12th, 1844.

Your Treatise on Navigation, I consider better calculated than any other, to meet the wants of those who navigate the ocean; but most particularly does it deserve the attention of our midshipmen, to whom it is recommended, from the fact of being the result of the labours of a brother officer, who, from experience, knew the defects of all previous books on the subjects.

I hope to see your book adopted as the text book in the service, by order of the head of the Navy Department.

Lt. M. F. MAURY, U. S. N.

Opinion of J. S. CHAUNCEY, Commander U. S. N., WASHINGTON, March 14th, 1844.

During my late cruise in the "Vandalia," I have had frequently to refer to Lt. Maury's "Treatise on Navigation," and have found it not only useful, but eminently calculated to supply a deficiency long existing in works treating of the subject. It explains clearly the principles upon which the rules are founded; and the illustrations of the theory of Navigation and Nautical Astronomy, are conducted with simplicity and conciseness, which should tend materially

Digitized by Google

to facilitate the student in acquiring a knowledge of both the theory and practice of the science of which it treats.

I consider the book as a valuable acquisition to the young naval officer, who is ambitious in the pursuit of the knowledge necessary to prepare him for the efficient discharge of his duties.

Lt. M. F. Maury, U. S. N.

Opinion of Lt. Oliver H. Perry, U. S. N. } Boston, April 6th, 1844. }

I most gladly bear testimony to the value of your "Treatise on Navigation:" believing that if introduced into our schools, it would raise the standard of Mathematical attainments, and induce some to pursue the subject in its higher branches. Its explanations of the principles of Nautical Astronomy render it a valuable key to the practical rules of Bowditch.

Lt. M. F. Maury.

Opinion of Commodore Wadsworth. } Washington, April 16th, 1844. }

I have not had an opportunity to examine your "Treatise on Navigation," so thoroughly as I wished; but I have seen enough to convince me that it is a very valuable work for the young officers of our Navy. The arrangement of the work is good, the illustrations appear complete, and the tables ample.

I hope it may, and I have no doubt it will become generally used in the Navy.

Lt. M. F. Maury, U. S. N.

BOOKS

PUBLISHED BY EDWARD C. BIDDLE,

No. 6 SOUTH FIFTH STREET, PHILADELPHIA.

PEALE'S GRAPHICS. Drawing reduced to its most simple principles, introductory to Writing, and to all the Arts, useful and ornamental; in five Books. By Rembrandt Peale, Professor of Graphics in the Central High School of Philadelphia. Three parts published.

LINEAR DRAWING BOOK; designed for the use of Schools and practical purposes. By Samuel Smith, Professor of drawing in St. Mary's College, Baltimore.

DRAWING BOOK OF FLOWERS AND FRUIT; with beautifully coloured illustrations. Designed for the use of Schools, private pupils, and Amateurs. By Mrs. Anne Hill.

BRIDGES' ALGEBRA. Last Edition.

JOHNSON'S MOFFAT'S NATURAL PHILOSOPHY.—A system of Natural Philosophy designed for the use of Schools and Academies, on the basis of Mr. J. M. Moffat, comprising Mechanics, Hydrostatics, Hydraulics, Pneumatics, Acoustics, Pyronomics, Optics, Electricity, Galvanism and Magnetism: With Emendations, Notes, Questions for Examination, &c. &c. By Prof. W. R. Johnson. 12mo.

N. B. The title of the above work has been changed from "Scientific Class Book, Part I."

JOHNSON'S MOFFAT'S CHEMISTRY.—An Elementary Treatise on Chemistry, together with Treatises on Metallurgy, Mineralogy, Crystallography, Geology, Oryctology and Meteorology; designed for the use of Schools and Academies; on the basis of Mr. J. M. Moffat: With Additions, Emendations, Notes, References, Questions for Examination, &c. &c. By Prof. W. R. Johnson. 12mo.

N. B. The title of the above work has been changed from "Scientific Class Book, Part II."

OSWALD'S ETYMOLOGICAL DICTIONARY of the English Language, on a plan entirely new. Revised and improved, and especially adapted to the purpose of teaching English Composition. By J. M. Keagy. 12mo.

MANUAL OF CLASSICAL LITERATURE from the German of John J. Eschenburg. With additions by Professor Fiske of Amherst College. The work comprises five parts:—1. Classical Geography and Chronology.

Digitized by Google

2. Mythology of the Greeks and Romans. 3. Greek and Roman Antiquities. 4. Archæology of Greek and Roman Literature and Art. 5. History of Ancient Literature, Greek and Roman. Fourth edition, much enlarged and improved; illustrated by twenty finely executed copper plates, and by wood cuts representing more than four hundred different objects. 8vo.

CLASSICAL ANTIQUITIES, being a portion of the Manual of Classical Literature, comprising the *first three parts*. Fourth edition, illustrated by thirteen finely executed copper plates, and by wood cuts representing about three hundred different objects. 8vo.

SUPPLEMENTAL VOLUME OF PLATES, illustrating the Manual of Classical Literature, containing thirty-two finely executed copper plates referred to in the "Manual," but not bound with that work. 8vo.

FRENCH LESSONS FOR BEGINNERS.—L'ABEILLE POUR LES ENFANS, ou Leçons Français, 1ère Partie; a l'usage des ecoles. 18mo.

ÆSOP'S FABLES IN FRENCH; preceded by a description of fifty animals, most of which occupy a place in the Fables themselves; and accompanied by a French-English Dictionary of all the words contained in both parts of the volume.

TREGO'S PENNSYLVANIA: being an account of the History, Geographical Features, Soil, Climate, Geology, Botany, Zoology, character and amount of Population, state of Education, form of Government, condition of Finances, nature and value of Productions, course and extent of Trade past and present, routes and cost of Rail-Roads and Canals, &c. of the *State;* with a separate description of *each County*. Illustrated by a copper-plate Map of the State, and by numerous Engravings on wood. By Charles B. Trego, member of the House of Representatives of Pennsylvania, late assistant State Geologist, member of the Am. Phil. Soc. &c.

THE PHILADELPHIA DIRECTORY, revised and corrected anually by A. M'Elroy.

THE COMMON SCHOOL JOURNAL OF THE STATE OF PENNSYLVANIA. Published under the supervision of the Superintendent of Common Schools of the Commonwealth. Professor J. S. Hart, Principal of the Central High School of Philadelphia, Editor. Issued monthly, in numbers of thirty-two pages 8vo., at one dollar per annum.

HOME BOOK OF HEALTH AND MEDICINE; being a popular treatise on the means of avoiding and curing diseases, and of preserving the health and vigour of the body to the latest period: including a full account of the Diseases of Women and Children, &c., by a Philadelphia Physician. 8vo.

UNIVERSAL BIOGRAPHICAL DICTIONARY, to which is added a Dictionary of the Principal Divinities and Heroes of Grecian and Roman Mythology, and a Biographical Dictionary of Eminent Living Characters.

SPEECHES OF PATRICK HENRY, FISHER AMES, WILLIAM PINCKNEY, and others. 1 vol. 8vo.

SPEECHES OF PHILLIPS, CURRAN, GRATTAN AND EMMETT. 1 vol. 8vo.

SPEECHES OF CHATHAM, BURKE, AND ERSKINE, to which are added the Arguments of Mr. Mackintosh in the case of Peltier; selected by a member of the Philadelphia Bar. 1 vol. 8vo.

SELECT SPEECHES OF THE RT. HON. GEORGE CANNING. Edited by Robert Walsh, Esq., with a biographical and critical introduction, by the editor. 1 vol. 8vo.

SELECT SPEECHES OF THE RT. HON. WILLIAM HUSKISSON, and of the RT. HON. WILLIAM WINDHAM. Edited by Robert Walsh, Esq. With a biographical and critical introduction, by the editor. 1 vol. 8vo.
